Background and aims: HAV and HEV are currently the most common causative agent of acute viral hepatitis in humans. Wild-type HAV and HEV has long been extremely difficult to culture in cells and only limited cell-adapted strains can be used for in vitro culture. The viral stocks used to infect animals are usually prepared directly from feces or liver homogenates collected from infected animals or humans. Using reverse generic system, either after many days or weeks in culture to collect adequate titers of infectious viral stocks or direct injection of in vitro transcribed (IVT) full-length viral genomic RNA (vRNA) into the liver is required to establish animal infection. These procedures are either time-consuming or warrant invasive operation which impede the efficiency, uniformity and quality control of the establishment of a tractable animal model. Therefore, a culture-free, robust and rapid approach for the establishment of in vivo infection is urgently warranted.

Method: By using this innovative LNP-based RNA delivery platform and full-length viral genome RNA (vRNA) system, we successfully encapsulated the full-length viral genome RNAs (vRNAs) of HAV and HEV into LNP, and established the corresponding animal models by intravenous injection of these LNP-vRNA formulations. The effect of the model was evaluated by detecting fecal detoxification, urine antigen, liver tissue HE staining, immunohistochemistry, transcriptome analysis and other experimental methods.

Results: We rationally prepared Lipid nanoparticle (LNP)-encapsulated full-length genomic RNA (vRNA) of HAV and HEV, and establishment of HAV and HEV infection was achieved after intravenous injection in susceptible animals. Upon LNP-vRNA injection, HAV and HEV infection resulted in rise of viral RNA in feces, liver or bile samples, or viral antigen in urine. $10 \mu\text{g}$ HEV RNA could induce successful infection in individual rabbit. Liver showed inflammatory infiltration and active transcriptional response against acute HEV infection. The antiviral efficacy of ribavirin and in vivo function of HEV genome mutation and deletion were validated in our model.

Conclusion: By using this innovative LNP-based RNA delivery platform and full-length viral genome RNA (vRNA) system, we successfully encapsulated the full-length viral genome RNAs (vRNAs) of HAV and HEV into LNP, and established the corresponding animal models by intravenous injection of these LNP-vRNA formulations. This novel approach enables rapid and efficient establishment of HAV and HEV in vivo infection in multiple animals, providing a powerful tool to investigate the pathogenesis of these enterically-transmitted hepatitis viruses as well as to evaluate specific countermeasures.

SAT-399

Immune profiling of HBsAg-specific B cells in CHB patients with HBsAg loss

Yifei Guo¹, Yue Guo¹, Yide Kong¹, Haoxiang Zhu¹, Jiming Zhang¹.
¹Department of Infectious Diseases, Shanghai Key Laboratory of Infectious Diseases and Biosafety Emergency Response, National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, Shanghai, China
Email: yfguo21@m.fudan.edu.cn

Background and aims: HBsAg loss, namely, the functional cure, is the optimal end point of current antiviral therapies. However, little is known about the frequency, phenotype and class-switching of HBsAg-specific B cells in chronic hepatitis B (CHB) patients with HBsAg loss. Here, we compare the HBsAg-specific memory B cells (HBs⁺ Bm cells) of CHB patients with and without HBsAg loss, as well as functional cure CHB patients with different anti-HBs levels.

Method: We included 42 treatment-naïve CHB patients without HBsAg loss (chronic HBsAg⁺), 94 interferon-treated CHB patients with HBsAg loss (chronic HBsAg⁻), and 20 healthy controls with or without HBsAg-vaccinated. Detailed characterization of memory B cell responses in peripheral blood was determined through high-dimensional flow cytometry. HBs⁺ Bm cells were identified and examined using fluorescently labeled HBsAg bait.

Results: No statistically differences in frequency were observed among vaccinated controls (median 0.09%), chronic HBsAg⁺ (median 0.14%), and chronic HBsAg⁻ (median 0.14%) patients. Similarly, the frequency did not differ significantly across all clinical phases of chronic HBV infection. Of note, we observed that the increased frequency of HBs⁺ Bm cells was accompanied by concordant elevation of anti-HBs levels, even though there was a trend, not statistical significance, towards elevated frequencies in patients with $10 \leq \text{anti-HBs} < 500$ IU/L compared with anti-HBs < 10 IU/L. A composite sample was generated by merging FCM results of HBs⁺ Bm cells with non-HBs⁺ Bm cells from CHB patients. The UMAP showed a clear segregation of HBs⁺ Bm cells from non-HBs⁺ Bm cells, indicating the distinct immune profiles of HBs⁺ Bm cells. Furthermore, compared with global memory B cells, a range of expression of inhibitory markers, including BTLA, CD11c, PD-1, CD22, and FcRL5 were increased, which were consistent with preliminary studies on impaired HBsAg-specific B cell function. When comparing the differences of HBs⁺ Bm cells in chronic HBsAg⁺ and chronic HBsAg⁻ patients, there were not significant differences in frequency of resting (CD21⁺CD27⁺), activated (CD21⁻CD27⁺), atypical (CD21⁻CD27⁻), and intermediate (CD21⁺CD27⁻) HBs⁺ Bm cells. Of note, expressions of T-bet and CXCR5 were decreased in chronic HBsAg⁻ patients. Analysis of class-switching of HBs⁺ Bm cells detected a trend towards elevated

proportion IgG⁺ HBs⁺ Bm cells in chronic HBsAg- compared with chronic HBsAg+ patients. For chronic HBsAg- patients, HBs⁺ Bm cells in patients with anti-HBs \geq 500 IU/L exhibited lower expression of CXCR5 and higher proportion of IgG⁺ than other two groups (10 \leq anti-HBs <500 IU/L and anti-HBs <10 IU/L).

Conclusion: HBs⁺ Bm cells exhibit a distinct immune profile compared to global memory B cells. Low expression of CXCR5 in HBs⁺ Bm cells might be associated with restored function and a favorable outcome.

SAT-402

Bemnifosbuvir is a potent HCV NS5B inhibitor with a favorable antiviral profile and high resistance barrier

Qi Huang¹, Dawei Cai¹, Steven Good¹, Nancy Agrawal¹, Jean-Pierre Sommadossi¹. ¹Atea Pharmaceuticals, Inc., Boston, United States

Email: huang.qi@ateapharma.com

Background and aims: Bemnifosbuvir (BEM), an oral prodrug of a guanosine nucleotide analog, has demonstrated highly potent, pan-genotypic, best-in-class *in vitro* antiviral activity against all hepatitis C virus (HCV) genotypes (GTs 1–5) tested. Viral resistance has emerged as an important consideration for direct-acting antivirals (DAAs) as it may impact efficacy of HCV infection treatment. The antiviral activity of BEM was profiled against a panel of sofosbuvir (SOF) non-structural protein 5B (NS5B) resistance-associated variants (RAVs) selected *in vitro* or identified in HCV patients. *In vitro* resistance selection was performed using HCV GT-1a and –1b replicon cells to identify NS5B RAVs potentially impacting BEM antiviral activity.

Method: *In vitro* resistance selection was conducted in the presence of G418 and gradually-increasing concentrations of AT-511 (free base of BEM). Cells from each passage were collected for genotypic analysis. Emerging NS5B substitutions (single or linked) were selected for phenotyping in transient replicon assays.

Results: Resistance selection in GT1b replicons identified C223H as the primary substitution that confers resistance to AT-511, which is the same mutant identified in GT-2a (JFH-1) replicons cultured in the presence of PSI-352938 or PSI-353661, two HCV nucleotide analogs that also generate the same active tri-phosphate AT-9010, in previous studies (Lam, JVI, 2011). C223H substitution requires two nucleotide mutations, which confers a higher barrier to resistance. Additional substitutions were identified in GT-1a (C316F, N444D, F574V, I585T) and GT-1b (F54I, N206S, E237G, T344I, Y586C). Phenotypic evaluation of both GT-1a and –1b mutations indicated that single amino acid changes did not significantly reduce AT-511 activity (up to 1.7-fold). However, a combination of amino acid changes in GT-1b (F54I, C223H, E237G, T344I, Y586C) conferred higher levels of resistance (up to 5.9-fold). In addition, SOF did not show cross-resistance to C223H, and only conferred weak resistance to the linked mutants.

Conclusion: BEM is at least 10-fold more potent than SOF across all genotypes tested and is not resistant to SOF RAVs (S282T, L159F/S282T). C223H was found to be the primary BEM RAV in GT-1b and multiple substitutions at other NS5B regions were required to confer meaningful resistance, suggesting a very high barrier to resistance for BEM. BEM is currently being evaluated in combination with ruzasvir (RZR), a highly potent pan-genotypic NS5A inhibitor, in a Phase 2 clinical trial (NCT05904470). Based upon the data demonstrated to date, it is expected that the BEM/RZR combination should have a more compelling antiviral profile against major HCV NS5A RAVs than current standard of care.

SAT-403

Vitamin D supplementation accelerated reduction of HBsAg levels in patients with chronic hepatitis B requiring treatment and in inactive carrier phase

Thitaporn Roongrawee¹, Sirinporn Suksawatamnuay², Panarat Thaimai², Prooksa Ananchuensook³, Supachaya Sriphoosanaphan⁴, Kessarin Thanapirom⁵, Piyawat Komolmit⁶. ¹Division of Gastroenterology, Department of Medicine, Faculty of Medicine, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; ²Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand; ³Chulalongkorn University, Division of Gastroenterology, Department of Medicine, Bangkok, Thailand; ⁴Institute for Liver and Digestive Health, University College London, London, United Kingdom; ⁵Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Bangkok, Thailand; ⁶Division of Gastroenterology, Department of Medicine, Faculty of Medicine, Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand

Email: thitagiftr@gmail.com

Background and aims: Low levels of vitamin D are prevalent among individuals with chronic hepatitis B (CHB) infection. Vitamin D is known to modulate the immune system and potentially influence the immune response to hepatitis B viral replication, as indicated by the quantitative hepatitis B surface antigen (qHBsAg)-a marker of viral replication and predictive indicator for functional cure. Previous studies established a correlation between vitamin D levels and qHBsAg levels. However, the direct impact of vitamin D supplementation on qHBsAg levels remains a subject of ongoing investigation.

Method: Retrospective data from HBV inactive carriers and CHB patients undergoing antiviral treatment with initially low vitamin D levels were analyzed. Quantification of qHBsAg levels before and after vitamin D supplementation over an 18-month period was conducted.

Results: Among 1069 CHB cases follow-up at King Chulalongkorn Memorial Hospital's liver clinic, complete data for qHBsAg and vitamin D levels were available for 203 patients. Of these, 88 were inactive carriers, and 115 were CHB patients. Vitamin D insufficiency (vitamin D levels 20–30 ng/ml) was observed in 77 patients, while 97 patients had vitamin D deficiency (vitamin D levels below 20 ng/ml). Pre-supplementation vitamin D levels averaged 19.5 \pm 4.8 ng/ml and significantly increased to 36.69 \pm 14.58 ng/ml post-supplementation ($p < 0.01$). Most patients received weekly vitamin D supplements at a dosage of 40, 000 IU/week (N 145; 71.43%), followed by 60, 000 IU/week (N 43; 21.18%) and 20, 000 IU/week (N 15; 7.38%), respectively. The average interval between qHBsAg measurements before starting vitamin D was 10.6 months and the average time after vitamin D initiation was 11.1 months. The level of qHBsAg demonstrated an 11.23% decrease before vitamin D supplementation, significantly reducing further to 18.20% post-supplementation ($p = 0.032$). Subgroup analysis revealed a significant decline of qHBsAg level in 88 inactive carriers (–9.23% vs –19.30%; $p = 0.028$) and in 79 patients with qHBsAg levels more than 1, 000 IU/ml (0.53% vs –14.30%; $p = 0.009$). However, CHB patients on antiviral treatment and patients with qHBsAg levels between 100 and 1, 000 IU/ml showed substantial reduction but lacked statistical significance (–12.77% vs –17.35%; $p = 0.422$, –13.77% vs –18.31%; $p = 0.257$, respectively).

Conclusion: This study demonstrates a significant decrease in qHBsAg levels following vitamin D supplementation, particularly prominent in individuals with high qHBsAg levels exceeding 1, 000 IU/ml and inactive carriers. These findings imply a potential enhancement of qHBsAg decline facilitated by vitamin D. The implications warrant further exploration if vitamin D's role in managing chronic hepatitis B, presenting avenues for future research.

The Lipidome in phenotyping hepatitis B infection ('LiPHe-B'): preliminary results from our pilot study

Marion Delphin¹, Susana Palma-Duran^{1,2}, Mariana Silva dos Santos¹, Emily Martyn¹, Elizabeth Waddilove¹, Emma Wall¹, Tongai Gibson Maponga³, Jacqueline Martin⁴, Catherine De Lara⁵, Paul Klenerman⁵, Eleanor Barnes⁵, James Macrae¹, Philippa C Matthews^{1,6}. ¹*the francis crick institute, london, United Kingdom*; ²*Department of Food Science, Research Center in Food and Development A.C, Hermosillo, Mexico*; ³*Division of Medical Virology, Stellenbosch University/National Health Laboratory Service Tygerberg Business Unit, cape town, South Africa*; ⁴*Department of Hepatology, John Radcliffe Hospital, oxford, United Kingdom*; ⁵*Nuffield Department of Medicine, Medawar Building for Pathogen Research, University of Oxford, oxford, United Kingdom*; ⁶*University College London, london, United Kingdom*

Email: marion.delphin@crick.ac.uk

Background and aims: Chronic Hepatitis B infection (CHB) kills 1 million people per year, due to liver fibrosis, cirrhosis, and hepatocellular carcinoma (HCC). Hepatitis B Virus (HBV) has been described as a 'metabovirus' for its close connection with host metabolism and lipids, but current biomarkers are blunt tools for risk assessment, and guidelines do not account for host and viral genetics, metabolic risk factors, and environmental influences contributing to liver disease. There is a need for improved risk-stratification that accounts for these parameters and can inform patient-stratified approaches. The liver is one of the most important organs in energy metabolism, and the origin of most blood lipids, potentially explaining why host lipid profiles could impact or reflect the antiviral immune response and HCC progression. We set out a pilot study to optimize methods and establish proof-of-principle for this approach in HBV, and to determine whether profiles differed between people living with HBV (PLWHB) vs healthy controls.

Method: Serum samples were obtained from PLWHB, enrolled at Oxford University Hospitals, UK (n = 60) (ethics ref.N17/01/013) and age and sex-matched healthy non-infected adults, from the Legacy Study, London UK (n = 60) (ethics ref.21/YH/0222). Meta-data were recorded at the time of recruitment, supported by Electronic Patient Records where available. Lipids were extracted using a modified Bligh-Dyer extraction method followed by Liquid Chromatography-Mass Spectrometry (LC-MS) analysis for lipidome profile. Data processing and statistical analysis were performed using Xcalibur (Thermo Scientific), MS-DIAL (v 5.1.230517), KniMet pipeline for MS-based and SIMCA 17 (Sartorius, Germany). Principal component analysis (PCA) and orthogonal partial least square-discriminant analysis (OPLS-DA) models were used to explore the differences in the lipidome between CHB and controls.

Results: Comprehensive lipid profiles were obtained for a pilot subset of 40/120 serum samples. Initial multivariate analyses revealed clear differences in the lipidomes of non-infected and infected individuals. Detected features were initially annotated by comparison of molecular and associated fragment ions to compound libraries (both in-house and commercial). Further lipid extraction and identification is currently ongoing, along with additional clustering analysis based on liver disease progression in patients.

Conclusion: Adults living with HBV have a distinct lipidome profile that distinguishes them from matched adult controls. Developing insights into lipid biomarkers may enhance our understanding of the mechanisms that determine infection outcomes and treatment response, support better patient-stratification risk assessment and guide evidence-based interventions.

SAT-405

Differential expression and sequence variants of sodium taurocholate cotransporting polypeptide (NTCP) do not affect HDV inhibition by Bulevirtide (BLV)

Simin Xu¹, Thomas Aeschbacher¹, Savrina Manhas¹, Chunfeng Li¹, Ross Martin¹, Yang Liu¹, Evguenia Maiorova¹, Hongmei Mo¹, Roberto Mateo¹. ¹*Gilead Sciences Inc, Foster City, United States*
Email: simin.xu@gilead.com

Background and aims: The bile acid transporter sodium taurocholate cotransporting polypeptide (NTCP) is a transmembrane protein expressed on the surface of hepatocytes in the liver. NTCP is also an entry receptor for hepatitis B virus (HBV) and its satellite hepatitis D virus (HDV). The HDV entry inhibitor bulevirtide (BLV) specifically binds NTCP and blocks HDV from entering hepatocytes. The goal of this study was to investigate the role of NTCP expression level and polymorphisms on BLV inhibition of HDV.

Method: Public data were analyzed to identify NTCP single nucleotide polymorphisms (SNPs) with a Minor Allele Frequency (MAF) >1% in United States (US) and global racial groups (White, Black, Asian, Latino). In addition, NTCP whole exon sequencing was performed on primary human hepatocytes (PHHs) from 50 US donors. These were further evaluated for NTCP expression, mRNA levels and HDV sensitivity to BLV in an in vitro phenotyping assay. PHHs from 33 PHH donors carrying identified NTCP SNPs and various expression NTCP levels were evaluated for HDV sensitivity to BLV in an in-vitro phenotyping assay.

Results: Six NTCP SNPs were observed in the public dataset with MAFs >1% in one or more racial group. Of these SNPs, 2 were non-synonymous (C800T, T668C) and 4 were synonymous (G225A, T627C, C960A, C111T). C800T (aaS267F) was found with a MAF of 3.6% in the Asian racial group in the global dataset. T668C (aaI223T) was found in the Black racial group in the US and global datasets with MAFs of 1.6% and 4.1%, respectively. Four NTCP variants were detected in the 50 PHH donors from the US. C800T (aaS267F) and T668C (aaI223T) non-synonymous SNPs were detected in PHHs from an Asian and Black donor, respectively. Synonymous SNPs G225A and T627C were detected in 4 donors (Black, n = 2; Latino, n = 1; White, n = 1) and 2 Black donors, respectively. NTCP surface protein levels varied 5.8-fold and mRNA levels varied 391-fold among the 50 PHH donors. BLV remained active against HDV on PHHs expressing all levels of NTCP and all NTCP SNPs observed in the 50 US donors.

Conclusion: BLV potently inhibits HDV regardless of naturally occurring NTCP sequence variants and differential NTCP expression levels.

SAT-406-YI

HBV dominance is associated with a distinct inflammatory milieu in HBV/HCV coinfection

Carlos Oltmanns^{1,2,3}, Moana Witte^{1,2,3}, Anika Wranke¹, Katja Deterding¹, Heiner Wedemeyer^{1,4,5}, Christine Falk⁶, Anke R.M. Kraft^{1,2,3,4,5}, Steffen Wiegand⁷, Markus Cornberg^{1,2,3,4,5}.

Email: oltmanns.carlos@mh-hannover.de

Background and aims: Hepatitis B (HBV) and C (HCV) virus coinfection is linked to a higher risk of cirrhosis and hepatocellular carcinoma (HCC) compared to mono-infection. Despite this, data is limited, and further investigation is needed to understand the underlying mechanisms. While patients are classified based on dominance patterns, the impact on the immune system remains largely unknown. It is recognized that HBV reactivation may occur following HCV clearance. This study aims to explore the potential immune interactivity between HCV and HBV by analyzing patterns of soluble immune mediators (SIM).

Method: Fifty-nine soluble immune mediators were measured in serum or plasma samples of 49 patients chronically infected with hepatitis B and hepatitis C virus. Patients were classified based on dominance patterns: HBV dominance (n = 8), HCV dominance (n = 22), HBV and HCV codominance (n = 11) and no dominance (n = 8).

Results: SIM expression was distinct based on different dominance patterns. HBV activity induced higher SIM expression and altered the soluble inflammatory milieu (22 SIM altered, $p < 0.05$). Altered pathways included JAK-STAT pathway ($p = 1.36 \times 10^{-20}$), IL-17 signaling ($p = 2.47 \times 10^{-13}$) and Th17 ($p = 1.69 \times 10^{-9}$) cell differentiation. CTACK ($r = -0.69$, $p = 7.02 \times 10^{-6}$) and SDF-1 α ($r = -0.55$, $p = 0.002$) correlated inversely with HCV-RNA.

Conclusion: Serologically classifying dominance patterns in HBV and HCV coinfection may manifest in a distinct soluble inflammatory milieu. Elevated HBV activity correlates with an increased expression of soluble immune mediators, particularly influencing the alteration of key signaling pathways such as JAK-STAT and the TH17/IL-17 axis. These changes play a crucial role in the development of liver fibrosis.

Long-term sustained decline of anti-HCV neutralizing antibodies in HIV/HCV-coinfected patients after therapy-induced HCV clearance

Daniel Sepúlveda-Crespo^{1,2}, Camilla Volpi^{1,3}, Rafael Amigot-Sánchez¹, Marta Quero-Delgado¹, María Yélamos⁴, Cristina Diez^{2,5,6}, Julián Gómez⁴, Víctor Hontañón^{7,8}, Juan Berenguer^{2,5,6}, Juan Gonzalez^{2,7,8}, Rubén Martín-Escolano^{1,2}, Salvador Resino Garcia^{1,2}, Isidoro Martínez^{1,2}. ¹Unidad de Infección Viral e Inmunidad, Centro Nacional de Microbiología, Instituto de Salud Carlos III, Madrid, Spain; ²Centro de Investigación Biomédica en Red en Enfermedades Infecciosas (CIBERINFEC), Instituto de Salud Carlos III, Madrid, Spain; ³Dipartimento di scienze farmaceutiche e biomolecolari, Università degli Studi di Milano, Milan, Italy; ⁴Departamento de Bioquímica y Biología Molecular, Facultad de Ciencias Químicas, Universidad Complutense, Madrid, Spain; ⁵Unidad de Enfermedades Infecciosas/VIH; Hospital General Universitario Gregorio Marañón, Madrid, Spain; ⁶Instituto de Investigación Sanitaria del Gregorio Marañón (IISGM), Madrid, Spain; ⁷Unidad de VIH; Servicio de Medicina Interna, Hospital Universitario La Paz, Madrid, Spain; ⁸Instituto de Investigación Hospital Universitario La Paz, (IdIPAZ), Madrid, Spain
Email: danisecre@hotmail.com

Background and aims: Cross-reactive neutralizing antibodies against hepatitis C virus (HCV), primarily targeting the E2 glycoprotein, play a crucial role in controlling and clearing HCV infection and protecting against HCV reinfection. This study aimed to evaluate the titers and the amplitude of anti-E2 antibodies (anti-E2-Abs) and neutralizing antibodies against HCV (anti-HCV-nAbs) in HIV/HCV-coinfected patients over five years after the sustained viral response (SVR) following IFN-based therapy (PEG-IFN α /RBV or PEG-IFN α /RBV/DAA) or IFN-free DAA therapy.

Method: We followed 76 HIV/HCV-coinfected patients for five years after antiviral therapy-induced SVR. Plasma levels of anti-E2-Abs and anti-HCV-nAbs against five HCV genotypes (Gt1a, Gt1b, Gt2a, Gt3a, and Gt4a) were determined using ELISA and microneutralization assays, respectively. Statistical analyses comparing the three follow-up time points (baseline, one-year, and five-year post-HCV

treatment) were performed using Generalized Linear Mixed Models. p values were adjusted using the False Discovery Rate (q-value).

Results: Compared to baseline, plasma anti-E2-Abs titers decreased at one year (1.9 to 2.3-fold, q-value < 0.001) and five years (3.4 to 9.1-fold, q-value < 0.001) post-HCV treatment. Plasma anti-HCV-nAbs decreased 2.9 to 8.4-fold (q-value < 0.002) at one year and 17.8 to 90.4-fold (q-value < 0.001) at five years post-HCV treatment. HCV-nAbs titers against Gt3a were consistently the lowest. Low anti-E2-Abs nonresponse rates were observed throughout the follow-up, while anti-HCV-nAbs nonresponse rates increased. At baseline, anti-HCV-nAbs were undetected in 4.0–5.3% of patients. At the five-year post-HCV treatment, nonresponse rates increased 1.8 to 13.5-fold (q-value < 0.05), with the highest nonresponse rate for Gt3a.

Conclusion: An overall decline in humoral responses against HCV (anti-E2-Abs and anti-HCV-nAbs) among HIV/HCV-coinfected patients at one- and five-years post-HCV treatment was observed, regardless of the analyzed HCV genotype. However, this decline was more pronounced for the anti-HCV-nAbs, particularly in the Gt3.

SAT-408

Molecular and functional analysis of a hepatitis B virus genotype C infection in a vaccinated individual

Maëlienn Delcourt¹, Peter Gowland², Christoph Niederhauser³, Daniel Candotti¹. ¹Dept of Virology-Henri Mondor Hospital-Paris-Est University-INSERM U955-IMRB-Team 18, Creteil, France; ²Interregional Blood Transfusion SRC, Laboratory Diagnostics and RandD Diagnostics, Berne, Switzerland; ³Interregional Blood Transfusion SRC, Laboratory Diagnostics and RandD Diagnostics, Berne, Switzerland
Email: daniel.candotti@inserm.fr

Background and aims: Global hepatitis B virus (HBV) vaccination is key to the WHO objective to eradicate hepatitis B by 2030. The present study investigates an acute HBV infection in a regular blood donor from Switzerland with a complete vaccination course (Engerix B; 2001/2002).

Method: HBV infection was monitored by testing for serological markers and HBV DNA in a 6-months follow-up. PreS/S region was sequenced after viral particle concentration. S amino acid substitutions-related phenotype was investigated by site directed mutagenesis and in vitro functional analysis.

Results: At index time, HBV DNA (6 IU/ml) was detected in the presence of anti-HBs (500 mIU/ml) as only serological marker. Anti-HBs level was 14 mIU/ml and all HBV markers were negative in the donation collected six months earlier. HBV subgenotype C1 strain supported recent HBV exposure in Thailand. Follow-up showed transient HBV viraemia, anti-HBs level increase (> 1 000 mIU/ml), and no HBsAg and anti-HBc seroconversion. PreS/S amino acid sequence was identical to a consensus sequence from HBV_C-infected Asian donors. The S protein had 19 aa substitutions, including 8 within MHR, compared to a HBV_{A2} consensus sequence. Substitutions S114T, T126I, N131T, and T143S were observed at positions previously associated with immune escape. Quasispecies distribution showed 6 sequences differing by only one aa (W35R, Q51Stop, L89P, I195R, and G202E x2) from the dominant sequence. W35R and I195R were associated with significantly lower HBsAg production and cellular retention. A sW36R substitution resulted in a similar HBsAg production phenotype. The potential function of this conserved WW motif in the S cytosolic domain was investigated further by replacing sW35 with aa carrying positive (H, K, and R) or negative (E) charged lateral, uncharged polar lateral (Q), and hydrophobic side chain (A, M, F, and W). W35K and W35Q lead to intracellular retention of HBsAg. W35K was associated to reduced HBsAg production and W35F substitution leads to no phenotypic change. Results of W35H, E, A, M are pending.

Conclusion: HBV genotype C infection was confirmed in a fully vaccinated individual and was associated with an efficient secondary anti-HBs response leading to transient viraemia without HBsAg and

POSTER PRESENTATIONS

anti-HBc seroconversion over six months. This supported previous study suggesting that anti-HBs-only occult HBV infection was associated to vaccine escape. Infection may be related to low level of anti-HBs at the time of virus contact and aa variability in S epitopes between HBV_C strain and HBV_{A2}-derived vaccine. In vitro neutralization analysis is ongoing for confirmation. Unusual mutations in S cytosolic domain were associated to HBsAg reduced production and intracellular retention. Further investigations are needed to clarify the potential function of the conserved sW35sW36 motif in HBsAg production and viral replication.

SAT-409

Whole-genome hepatitis B virus sequencing at low viral loads from serum and dried blood spot using a multiplexed tiled amplicon approach

Republic of (formally known as Zaire)
Email: sheila.lumley@trinity.ox.ac.uk

Background and aims: Hepatitis B Virus (HBV) sequencing can be used to investigate viral transmission, evolution and polymorphisms linked to adverse outcomes such as resistance associated mutations (RAMs) and vaccine escape mutations (VEMs). However currently it is not possible to sequence full HBV genomes from approximately half of people with detectable HBV viral loads (VL), due to low median VL v.s. relatively high VLs required for full genome sequencing, high host background, genome structure and viral diversity. For the first time, we utilised an amplicon sequencing approach based on the ARTIC SARS-CoV-2 sequencing protocol for targeted full-genome HBV sequencing. We sequenced eight overlapping 500 bp amplicons to generate high quality consensus genomes from a range of VLs, including low VL samples, which it was previously not possible to sequence.

Method: HBV-specific primers were designed using a developmental version of PrimalScheme3. A multiple sequence alignment was generated from 2001 genomes and from this 94 primers were selected for each amplicon in order to cover the diversity present, resulting in the amplification of 8 amplicons generating a theoretical 100% genome coverage due to the circular genome. Plasma and dried blood spot (DBS) clinical samples with HBV VL 1.5–8.4 log (10) IU/ml from the UK and Democratic Republic of Congo were sequenced. Amplification and library preparation were performed by adapting the nCoV-2019 LoCost v3 sequencing protocol (Quick et al. 2020); 12 UK and 35 DRC samples multiplexed per run. Samples were sequenced on an Oxford Nanopore MinION with flowcell chemistry v10.4.1. Data were basecalled and demultiplexed using guppy (6.5.7). To enable compatibility with artic fieldbioinformatics (1.2.4), which generated the draft consensus genomes, primer.bed files were modified using primalhelper (1.0.0). We calculated genome coverage (at 20x depth) using samtools and bedtools.

Results: 47 clinical samples were sequenced. For samples with VL above 3 log (10) IU/ml, full length HBV genomes were recovered (100% coverage). For samples with VL as low as 1.5 log (10) IU/ml we were still able to achieve 90% genome coverage; the reduction in % coverage was due to lower sequencing depth of one amplicon. Genotypes A-E were identified, and data demonstrated distinct transmission patterns between households. We were able to call polymorphisms at sites of previously reported RAMs and VEMs.

Conclusion: We developed a simple, inexpensive targeted sequencing method to generate full-length HBV genomes at low VLs, which have previously been challenging to sequence. This method is readily deployable in resource-limited settings due to use of the MinION, and can also be easily adapted to other sequencing platforms. This data was used to call genotypes, RAMs, VEMs and perform phylogenetic analysis in previously difficult to sequence samples.

SAT-410

Establishment of a highly effective in vitro model for HBV genotype E infection

Rodrigue Kamga Wouambo¹, Felix Lehmann², Maria Pfefferkorn¹, Madlen Matz-Soja^{1,3}, Thomas Berg¹, Dieter Glebe⁴, Florian van Bömmel¹. ¹Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; ²Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Institute of Virology, Berlin, Germany; ³Rudolf-Schönheimer-Institute for Biochemistry, Leipzig, Germany; ⁴Institute for Medical Virology, National Reference Centre for Hepatitis B viruses and Hepatitis D viruses, Justus Liebig University Giessen, Giessen, Germany
Email: rodrigue.kamgawouamba@medizin.uni-leipzig.de

Background and aims: Hepatitis B virus genotype E (HBV-E) is highly prevalent in Africa and associated with a higher viral replication and higher risk of hepatocellular carcinoma development compared to other HBV genotypes. Although Africa has a disproportionately high burden of hepatitis B, studies concerning this genotype are still under-represented. Our project aims at establishing an effective in vitro model for HBV-E to better understand its biomarker production and pathogenesis.

Method: The 1.1 and 1.5mer overlength HBV DNA constructs were engineered by fast cloning as previously described (Li et al. 2011). In brief, the primers for insert amplification were designed with insert-specific sequences and additional 15–17 bases overlapping with the vector-ends. The 1.5mer was generated from the 1.1mer template and the plasmids were transfected with variable ratios to the transfection reagent (2:1; 3:1; and 4:1) into HepG2-hNTCP cells to produce HBV-E viral particles. Viral particles were concentrated by ultrafiltration using Vivaspin[®] 20, 300, 000 MWCO PES (Sartorius) and thereafter tested for infectivity in vitro. HBV DNA, HBV RNA, HBeAg and HBsAg composition were quantified from supernatant collected either every 2 or 7 days during transfection or infection experiments.

Results: Transfection of both HBV-E plasmids resulted in successful secretion of HBeAg and HBsAg, with a higher expression from the 1.5mer plasmid. Transfecting 1.5mer at different ratios (2:1; 3:1 and 4:1) revealed similar mean levels of HBV DNA (8.7; 8.19; 8.02 [log₁₀cp/ml]), HBV RNA (5.05; 4.4; 4.8 [log₁₀cp/ml]) and total HBsAg (45.92 ± 7.2; 40.94 ± 3.16; 46.9 ± 4.02 [ng/ml]) at 8 dpi. Interestingly, mean LHBs levels and proportions of secreted HBsAg in supernatant were 3-fold higher using transfection ratio 3:1 (2.7 ng/ml and 6.32%) compared to 2:1 (0.79 ng/ml and 1.68%) and 4:1 (0.72 ng/ml and 1.64%). In vitro infection with the generated HBV-E viruses (Week 5, MOI=200) lead to de novo infection; HBV DNA and RNA levels decreased from input (7.30 and 4.89 log₁₀cp/ml) to wash-out (3.89 and 0 log₁₀cp/ml) and showed a stable increase to 5.25 and 3.16 log₁₀cp/ml after 10 dpi follow by a sustained expression until 22 dpi.

Conclusion: The newly engineered HBV-E plasmids can be transfected in cell culture and used to generate infectious and replicating HBV-E viruses for in vitro analysis. Our model is ready-for-use in further studies on HBV replication and drug efficacy testing concerning HBV-E.

SAT-411

Absorption, distribution, metabolism, and excretion of [14C]-Bemnifosbuvir in the rats

Alex Vo¹, Steven Good¹, Nancy Agrawal¹, Jean-Pierre Sommadossi¹,
¹Atea Pharmaceuticals, Inc., Boston, United States
 Email: vo.alex@ateapharma.com

Background and aims: Bemnifosbuvir (BEM), a phosphoramidate oral prodrug of a unique, 6-modified guanosine nucleotide with potent antiviral activity against the RNA-dependent polymerase (RdRP) of several single stranded RNA viruses, is currently in development for the treatment of COVID-19 and HCV (in combination with the NS5A inhibitor ruzasvir). The mass balance, excretion, and metabolism of [¹⁴C]-BEM were characterized in normal and bile-duct cannulated (BDC) rats after a single oral dose.

Method: Male SD and LE rats received a single dose of [¹⁴C]-BEM at 60 mg/kg (200 µCi/kg). Urine and feces were collected through 168 h post-dose while plasma was collected for up to 48 h post-dose in normal rats. Urine and feces were collected for up to 96 h post-dose in BDC rats. Radioactivity was quantified by liquid scintillation counting. Tissue distribution was determined by quantitative whole-body autoradiography.

Results: The primary route of elimination of radioactivity was in the urine (50%) and feces (41%) in normal rats, and in the urine (43%), feces (35%), and bile (19%) in BDC rats, with total recovery of radioactivity of 91% in normal rats and 97% in BDC rats. BEM was widely distributed, with quantifiable levels present in many tissues through 24 h. In general, levels in tissues were similar to or lower than those in blood. Relatively high tissue levels were observed in the kidneys, liver, thymus, and small intestine. Low tissue levels were observed in brain, spinal cord, and bone. Concentrations in the eye lens were below the level of quantification. In general, the average elimination half-life for most tissues was <18 hr with no evidence for long-term retention or irreversible binding in skin or eye (uvea). BEM undergoes multistep metabolic activation to its active triphosphate (TP) metabolite AT-9010, which is found intracellularly. The major plasma circulating metabolites were AT-229 and AT-273. In urine, the major components were AT-229, AT-273, and AT-219. In bile, the major metabolite was AT-551. In feces, the major components were AT-229 and AT-273.

Conclusion: Following a single oral dose in rats, BEM has favorable overall ADME properties, including good bioavailability (>60%) and wide distribution to tissues with low penetration into the brain. BEM was highly and rapidly metabolized to the metabolite AT-273, which was a surrogate for the intracellular pharmacologically active TP.

SAT-412

Low risk of drug-drug interactions for Ruzasvir based upon in vitro metabolism and transporter interaction studies

Alex Vo¹, Jocelyn Yabut², Michael Hafey³, Hui Wan², Nancy Agrawal¹,
 Jean-Pierre Sommadossi¹. ¹Atea Pharmaceuticals, Inc., Boston, United States; ²Merck and Co., Inc., West Point, United States; ³Merck and Co., Inc., Rahway, United States
 Email: vo.alex@ateapharma.com

Background and aims: Ruzasvir (RZR), a potent small molecule inhibitor of hepatitis C nonstructural protein 5A (NS5A), is currently being developed for the treatment of hepatitis C virus (HCV) in combination with bemnifosbuvir, a potent nucleotide prodrug inhibitor of the RNA-dependent RNA polymerase (RdRp) of HCV. The potential of RZR to mediate drug-drug interactions (DDIs) via cytochrome P450 (CYP) metabolizing enzymes and transporters was evaluated *in vitro*.

Method: RZR was incubated *in vitro* with human liver microsomes, hepatocytes, and transporter transfected cells or membrane vesicles to evaluate its interaction with relevant enzymes/transporters.

Results: *In vitro* CYP reaction phenotyping suggested that CYP3A was the primary enzyme involved in the hepatic oxidative metabolism of RZR; however, the extent of CYP-mediated metabolism was observed

to be very low *in vivo*. RZR did not exhibit direct nor time-dependent inhibition of any major CYP450 enzymes at concentrations up to 10 µM. In human hepatocytes, RZR did not significantly induce CYP1A2, CYP2B6, or CYP3A4 mRNA. RZR inhibited P-gp-mediated digoxin transport and BCRP-mediated methotrexate uptake with an IC₅₀ of 0.049 µM and 0.27 µM, respectively. RZR inhibited uptake of pitavastatin and sulfobromophthalein mediated by OATP1B1 and OATP1B3 with an IC₅₀ of 0.092 µM and 0.052 µM, respectively. RZR also inhibited BSEP transporter with IC₅₀ of 0.37 µM. RZR did not exhibit any inhibition on OAT1, OAT3, and OCT2 transporters.

Conclusion: Based on *in vitro* data and static DDI risk assessment models, RZR has low potential to be a perpetrator of DDI via inhibition or induction of CYP450. Likewise, it has low potential to inhibit OATP1B1 and OATP1B3. The relevance of BSEP inhibition to DDIs is limited. However, RZR may be a perpetrator of DDI with P-gp and BCRP, which warrants further investigation *in vivo*.

 Email: philippa.matthews@crick.ac.uk

Background and aims: There are approximately 80 million people living with chronic Hepatitis B virus (HBV) in the WHO Africa region, but few seroepidemiology data to guide public health and clinical management strategies in African populations, for whom HBV elimination goals are still far from reach. We set out to investigate HBV infection markers in a rural population in South Africa.

Method: The EVOLVE-HBV ('Evaluation of Vukuzazi LiVEr disease') study used stored samples and biometric data collected by the Vukuzazi programme in KwaZulu Natal, South Africa. Vukuzazi enrolled participants who were ≥15 years old between May 2018 and March 2020. We selected 500 participants, stratified by sex, HIV status and age, to include adolescents and younger adults (born after routine HBV vaccine roll out started in South Africa from 1995 onwards). We screened plasma samples (according to availability) for HBV surface antigen (HBsAg), HBV core antibodies (anti-HBc) and HBV surface antibodies (anti-HBs). Two-tail significance tests were run at a 95% confidence interval using ANOVA and T-tests to determine differences in HBV biomarkers by age, sex and HIV status.

Results: Among 500 individuals in this study, 277 (55.4%) were female, 231 (46.2%) were living with HIV infection, and the median age was 31 years (IQR: 25–50). HBV infection (HBsAg) was present in 25/491 (5.1%) samples tested. Of the 25 participants who were HBsAg positive, 15/25 (60%) were male, median age was 46 years (IQR 28–55), 10/25 (40%) were HIV positive, and anti-HBc was present in 17/23 (73.9%). HBsAg was more likely to be positive in older participants (p = 0.004).

POSTER PRESENTATIONS

The overall prevalence of anti-HBc was 155/479 (32.4%), highlighting a high rate of exposure in this population. In this group, 84/155 (54.2%) were female, 75 (48.4%) HIV positive and median age was 50 years (39–61). Anti-HBc was more likely to be positive in older participants ($p < 0.001$).

There were 171/493 (34.7%) participants with anti-HBs titre > 10 mIU/ml, of whom 101/171 (59.1%) were female, 86 (50.3%) were HIV positive, and median age was 46 years (IQR 28–57). Vaccine-mediated immunity could be inferred in those with anti-HBs > 10 mIU/ml but HBsAg and anti-HBc negative; this serostatus was present in only 44/493 (8.9%) although our cohort was selected to include a cross-section of the population who should have received routine immunisation. Anti-HBs status was more likely to be positive in older participants ($p < 0.001$).

HBsAg, anti-HBc and anti-HBs were not associated with sex or HIV status ($p > 0.05$ for all).

Conclusion: In this population previously neglected by HBV research and clinical services, exposure to HBV is high, but only a minority of participants had evidence of vaccine-mediated immunity. Rapid scale-up of vaccination, diagnosis and treatment of HBV infection will be needed to make progress towards 2030 elimination goals.

SAT-414

Hepatitis B virus particles in serum contain minus strand DNA and degraded pregenomic RNA of variable and inverse lengths

Johan Ringlander¹, Sebastian Malmström¹, Anders Eilard¹, Lucia Gonzales Strömberg¹, Joakim Stenbäck¹, Maria Andersson¹, Simon B. Larsson¹, Michael Kann¹, Staffan Nilsson¹, Kristoffer Hellstrand¹, Gustaf Rydell¹, Magnus Lindh¹. ¹Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
Email: johan.ringlander@gu.se

Background and aims: Quantification of hepatitis B virus (HBV) RNA in serum has emerged as a complementary clinical marker, in particular for the monitoring of the effect of antiviral therapy. However, the nature of RNA particles and their composition of RNA remains incompletely known.

Method: We have used droplet digital PCR (ddPCR) assays that target three gene segments to quantify HBV RNA and HBV DNA in serum samples from 75 patients with chronic HBV infection.

Results: The HBV RNA levels were higher in the core than in the S and X regions (median 7.20 vs. 6.80 and 6.58 log copies/ml; $p < 0.0001$), whereas HBV DNA levels showed an inverse gradient (7.71 vs. 7.73 and 7.77 log copies/ml, $p < 0.001$). By quantification in core on average 80% of the nucleic acid was DNA. The core DNA/RNA ratio was associated with viral load and genotype. In individual patients with paired samples, the relationships between core, S and X RNA levels were stable over time ($n = 29$; $p = 0.006$).

Conclusion: The results suggest that pregenomic RNA is completely reverse transcribed to minus DNA in $\approx 75\%$ of the virus particles, whereas the remaining 25% contain both RNA and DNA of lengths that reflect variable progression of the polymerase.

SAT-415

Metabolic alteration linked to antiviral treatment response in 3D in-vitro model system of hepatitis B virus infection

Abhishak Gupta¹, Nupur Sharma², Sadam H Bhat¹, Jaswinder Maras¹. ¹Institute of Liver and Biliary Sciences, New Delhi, India; ²Institute of Liver and Biliary sciences, New Delhi, India
Email: abhigupta78@gmail.com

Background and aims: Hepatitis B virus (HBV) infection is a global health concern. Metabolic alterations during HBV antiviral reflect the treatment response in liver/hepatocytes remains unclear. Delineation of the metabolic changes in 3D in-vitro model system could help in characterization of cellular metabolic response and clearance of HBV infection. The primary aim was to develop a 3D model system using HepG2.2.15 and metabolic alteration during anti-viral treatment.

Method: 3D in-vitro model was developed for HepG2.2.15 by culturing them for 3 days. ETV at a dose of 1 and 10 micromolars was used for treatment and analyzed post 24, 48 or 72 hrs for the metabolic changes and viral markers. HBsAg, HBeAg and HBV DNA quantification were performed. Secretory metabolites from supernatants were extracted and analyzed using UPLC-HRMS based on comparative metabolomics coupled with pattern recognition methods and network pathway. Significant changes in the secretome were identified using WMCNA and the metabolite module specific to treatment response (temporal) or HBV infection was subjected to pathway analysis and correlation to ETV treatment dynamics.

Results: A 3D in-vitro model system was established with approx 20 K cells/organoids. ETV treatment both at 1 and 10 micromolars significantly lowered antigen secretion, virion production and HBV DNA synthesis without affecting cell viability in HepG2.2.15 organoids. HBsAg, HBeAg, and HBV DNA secretion were decreased temporally from 24 to 72 hrs ($p < 0.05$). WMCNA of the secretome led to the identification of 5 metabolite modules. ETV treatment temporally down regulated 83 metabolites linked to inflammatory Tryptophan metabolism (5-Hydroxy-N-formylkynurenine; Indolepyruvate), Sphingolipid metabolism, Arachidonic acid metabolism, Amino-acid metabolism and Lipid metabolism and others ($FC > 1.5$, $FDR < 0.01$, $p < 0.05$). Metabolites significantly increased and linked with treatment response were mainly involved in vitamin metabolism (Pantothenate and CoA biosynthesis, riboflavin, ascorbate and others), amino acid metabolism (Arginine, proline, glycine and others), Taurine and hypotaurine metabolism, and energy metabolism (pentose phosphate pathways) and others ($p < 0.05$). Secretome analysis showed that HBV infection induced inflammatory and oxidative metabolic pathways were significantly hampered. Further, increase in energy and amino acid metabolism post ETV treatment correlates with the inhibition of HBsAg/HBeAg expression and HBV replication.

Conclusion: 3D in-vitro model reflects changes in the secretory metabolite correlate to anti-viral treatment response and could be used for monitoring HBV replication/infection and development strategies for antiviral.

SAT-418

Prevalence of hepatitis C virus infection in a nursing home: a frequently overlooked submerged population

Paolo Gallo¹, Giulia Di Pasquale², Valentina Flagiello², Antonio De Vincentis², Francesca Terracciani², Antonio Picardi², Umberto Vespasiani-Gentilucci², Raffaele Antonelli Incalzi². ¹Fondazione policlinico universitario Campus bio-medico, Rome, Italy; ²Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy
Email: paolo.gallo@policlinicocampus.it

Background and aims: Despite the therapeutic success achieved through direct-acting antiviral agents, a significant number of individuals with undiagnosed hepatitis C virus (HCV) infection, often referred to as the “submerged” population (comprising institutionalized aged subjects living in nursing homes), persists. The objective of this study is to assess the prevalence of HCV antibodies and infection among patients residing in the Italian Hospital Group (IHG) Nursing Home in Guidonia Montecelio, Rome.

Method: The study was conducted across Extensive and Intensive Care Unit, Alzheimer Unit, Geriatric Unit, and Psychiatric Disorders Unit. All participants provided written consent to participate. Collected data encompassed patients' sociodemographic details, blood test results, and risk factors for HCV infection. Anti-HCV testing was done with Advanced Quality Rapid capillary test, followed by confirmation through a serum test. Anti-HCV positive testing has been followed by an HCV-RNA test. Descriptive statistics were employed to present the data, and logistic regressions were applied to assess risk factors for anti-HCV positivity.

Results: 434 patients were included. Both capillary and serum anti-HCV positivity were identified in 13 patients (3%), while the

prevalence of infection was 2.3%. Notably, positive patients exhibited a predominance of males and a younger age compared to their anti-HCV negative counterparts. The Psychiatric unit displayed the highest prevalence, with 46% of the cases (6 out of 13 patients). Logistic regression analysis identified several significant associations with anti-HCV positivity. Age (OR 0.96, 95% CI 0.93–0.99, $p = 0.01$), sex (OR 0.26, 95% CI 0.06–0.88, $p = 0.04$), hepatitis B virus (HBV) infection (OR 20.75, 95% CI 3.95–91.7, $p < 0.001$), dementia (OR 0.14, 95% CI 0.02–0.55, $p = 0.01$), smoking (OR 6.50, 95% CI 2.09–22.8, $p < 0.001$), and injection drug use (OR 10.5, 95% CI 1.59–51.09, $p = 0.005$) were all identified as significantly associated with anti-HCV positivity. Multivariate analysis confirmed only HBV infection (OR 13.7, 95% CI 1.82–94.8, $p = 0.008$) and smoke (OR 6.23, 95% CI 1.12–40.5, $p = 0.04$) as independently associated with the positivity.

Conclusion: Our findings reveal a 2.3% prevalence of HCV infection among people living in the Nursing Home; anti-HCV positivity was negatively associated with age and positively associated with dementia. Notably, the highest prevalence was observed in psychiatric patients, who not only exhibited increased susceptibility to HCV infection but were also younger compared to the general Nursing Home population. These preliminary data advocate that institutionalized (particularly psychiatric) patients should be included in HCV infection screening program in the submerged populations.

SAT-419

Transcriptomics reveals the regulation mechanism of the Chinese herbal TiaoGanJianPijieDu formula on inhibiting hepatitis B virus replication in mice

Ningyi Zhang¹, Xu Cao¹, Hening Chen¹, Jiaxin Zhang², Xiaoke Li², Xiaobin Zao³, Yong'an Ye². ¹Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; ²Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China; ³Dongzhimen Hospital, Beijing University of Chinese Medicine, Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China
Email: ningyi0202@163.com

Background and aims: Chronic Hepatitis B (CHB) is a chronic inflammatory liver disease caused by hepatitis B virus (HBV) infection. The Chinese herbal TiaoGanJianPijieDu formula (TGJP), a representative formula of traditional Chinese medicine (TCM) “immune incubation” therapy, has been widely used in the clinic and proved to be effective in the treatment of CHB. However, the underlying mechanism of TGJP is still unclear and needs to be further explored, which is the purpose of this study.

Method: HBV replicating mice was applied for animal model and treated with intragastric administration of distilled water (1 ml/10 g) or TGJP solution (0.33 g/ml) for 16 weeks. The therapeutic effect of TGJP on CHB was examined by serum HBV biomarker assay, Immunohistochemical (IHC) and qPCR. Hepatic tissue transcriptomic analysis was used to investigate the anti-HBV mechanism of TGJP on CHB. Gene Ontology (GO) and Kyoto Encyclopaedia of Genomes (KEGG) were used for further functional enrichment analysis.

Results: We established a mouse model by hyperbaric hydrodynamic injection (HDI) of 1.2-fold HBV plasmid DNA into the tail vein. Serum HBsAg was measured 48 hours after modelling, and serum HBsAg-positive animals were considered successfully modelling. Compared to the model, the serum HBsAg and HBeAg level were significantly decreased in the TGJP group after 5-week TGJP treatment. Hepatic HBV antigens IHC staining and qPCR showed that TGJP significantly enhanced clearance of hepatic HBsAg and HBeAg deposition and significantly inhibited the relative expression of total HBV DNA and HBV RNA, as compared with the model group. From the second week of TGJP treatment, serum ALT and AST levels in the TGJP group were significantly higher than those in the model group and remained elevated until the fifth week. The decline in serum HBsAg and HBeAg

levels followed the elevation of liver transaminases, suggesting finite liver inflammation may promote HBV clearance. Transcriptome analysis showed that there were 275 differentially expressed genes (DEGs) being identified between model group and TGJP group, including 128 up-regulated genes and 296 down-regulated genes. Heatmap suggested that there were significant differences in HBV-replicating mice liver after TGJP treatment compared with the model group. GO enrichment analysis showed that the top 20 enriched functions were mainly related to the activation and migration of immune cells. KEGG enrichment analysis of DEGs showed that the top 3 enriched pathways were mainly involved in the interaction between viral proteins and cytokines and their receptors, cytokine-cytokine receptor interactions, chemokine signalling pathways, which were closely related to the regulation of innate immunity.

Conclusion: Transcriptomics analysis showed that TGJP exerts an inhibition effect on HBV replicating in mice by regulating host immune function, especially innate immune.

SAT-420

The Chinese herbal TiaoGanJianPijieDu formula exerts an inhibition effect on hepatitis B virus replication by regulating hepatic CCL2-CCR2 signaling pathway and inducing immune-inflammatory response

Ningyi Zhang¹, Hening Chen¹, Xu Cao¹, Xiaobin Zao², Yong'an Ye³. ¹Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; ²Dongzhimen Hospital, Beijing University of Chinese Medicine, Key Laboratory of Chinese Internal Medicine of Ministry of Education and Beijing, Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; ³Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing University of Chinese Medicine, Liver Diseases Academy of Traditional Chinese Medicine, Beijing, China
Email: ningyi0202@163.com

Background and aims: Chronic hepatitis B (CHB) are a chronic inflammatory liver disease with host immune dysfunction caused by hepatitis B virus (HBV) infection. The Chinese herbal TiaoGanJianPijieDu formula (TGJP) has been widely used in clinical practice and has performed well in the treatment of CHB. However, the underlying mechanism of the TGJP for CHB remains to be studied. In this study, we aimed to explore the mechanism of TGJP in CHB treatment and to explore the targets and pathways of TGJP in modulating immunity.

Method: HBV-replicating mouse was applied as animal model, given TGJP gavage for 16 weeks. Ultra performance liquid chromatography-mass spectrometry/mass spectrometry (UPLC-MS/MS) identified the major components of TGJP. Transcriptomic was used for TGJP mechanism further study. The key pathways and putative targets of TGJP were obtained by network pharmacology analysis and transcriptomic. We validated the putative targets and key pathways of TGJP by immunohistochemistry (IHC), enzyme-linked immunosorbent assay (ELISA) and qPCR.

Results: We identified 174 active components of TGJP by UPLC-MS/MS, then screened 1043 targets of TGJP and 10019 CHB disease targets via public databases. Transcriptomics screened 275 differentially expressed genes in the livers of model and TGJP mice. We intersected above targets and obtained 14 key targets of TGJP in CHB treatment. Based on network pharmacology and transcriptomics analysis, we selected CCL2 as the key gene and CCL2/CCR2 axis as the key pathway for further research. GEO dataset validates the critical role of CCL2 in CHB. Animal experiments confirmed that compared with the model group, the serum and liver CCL2 levels of HBV replicating mice in the TGJP group were significantly higher than those in the model group, and the relative expression of *Ccl2* and *Ccr2* in liver tissues of mice were significantly higher. IHC results showed a significant increase of CD68⁺ and CCR2⁺ macrophages count in the liver tissue of the TGJP group compared with the model and control groups. Macrophages performs the role of inducing immune-inflammatory responses and activating adaptive immunity. By gene

POSTER PRESENTATIONS

set enrichment analysis, we found that TGJP upregulated inflammatory and immune response signalling pathways, which was confirmed by qPCR. Compared with the model group, TGJP up-regulated the expression of inflammatory factors such as *Cxcl10*, *Il33* and *Ifnlr1*, and down-regulated the expression of *Il10*. IHC also showed that CD8⁺ T cells were significantly increased in the TGJP group compared with the model group and the control group, suggesting that adaptive immunity was activated.

Conclusion: TGJP plays an anti-HBV role by upregulating the intrahepatic CCL2-CCR2 signalling pathway, promoting macrophage chemotaxis to the liver, inducing hepatic immune-inflammatory responses, and activating adaptive immunity.

SAT-421

Hepatitis B core related antigen in South Africa and the United Kingdom-does one size fit all?

Email: louise.downs@exeter.ox.ac.uk

Background and aims: Hepatitis B core related antigen (CrAg) has been associated with disease outcomes in chronic hepatitis B infection (CHB). To date, only the PROLIFICA study (Gambia), has assessed CrAg in Africa and no studies have compared CrAg in different continents. Here we aimed to examine how CrAg varies between cohorts in South Africa (SA) and the United Kingdom (UK) and investigate the association between CrAg and liver outcomes.

Method: Serum samples and clinical metadata were obtained from adults with CHB at Oxford University Hospitals, UK (n = 142), and Tygerberg Hospital in Cape Town, SA (n = 121) (ref. 09/H0604/20 and N17/01/013 respectively). HBV DNA, CrAg, HBsAg, HBeAg and ALT were measured. Liver health was assessed using APRI, Fib-4 and elastography. Associations between liver health and CrAg in the two cohorts were interrogated using complete-case logistic regression

with CrAg (linear) and cohort (binary) as covariates against (binary) liver health indicators.

Results: The UK and SA cohorts were of similar age (median 40 and 39 years respectively, p=0.2) and sex (46% and 45% female respectively, p=0.8). Comparing UK and SA cohorts, CrAg levels were lower in the UK (3.4 vs 3.8 log₁₀ IU/ml, p < 0.002), fewer people in the UK were HBeAg positive (12% vs 35%, p < 0.001) and fewer UK patients were on nucleoside analogue (NA) treatment (31% vs 65%, p < 0.001). HBV DNA was overall higher in the UK cohort, but more people in the SA cohort had HBV DNA >200,000 IU/ml (26% vs 5.6%, p < 0.001). By univariate analysis, CrAg was significantly correlated with HBV DNA in both cohorts (p < 0.0001) but there was no significant difference in CrAg between those on and off NA therapy in each cohort. We derived heatmaps to explore the extent to which CrAg correlated with markers of liver outcome within each cohort. Within the UK cohort, there was no significant correlation between CrAg and any liver parameter. Within the SA population, there was a significant positive correlation between CrAg and liver inflammation (ALT, p < 0.05). The strength of any association of CrAg with liver disease outcome did not significantly vary between cohorts.

Conclusion: Despite similar age and sex structures, HBV characteristics and CrAg distribution significantly differed between cohorts from the UK and SA. We observed no significant correlation between liver fibrosis or cirrhosis and CrAg, although liver inflammation by ALT was positively correlated with CrAg in SA. Associations may be influenced by HIV infection and other genetic, immunological or environmental factors. This novel comparison between geographical settings identifies knowledge gaps in interpretation of CrAg in different population groups.

SAT-422

E-selectin levels in patients with chronic hepatitis C

Petr Husa, Jr^{1,2}, Svatava Snopkova^{1,2}, Jiřina Zavřelová³, Filip Zlámál⁴, Radek Svačinka^{1,2}, David Vydráň^{1,2}, Petr Husa, Sr.^{2,5}. ¹Department of Infectious Diseases, University Hospital Brno, Brno, Czech Republic; ²Faculty of Medicine, Masaryk University, Brno, Czech Republic; ³Department of Hematology, University Hospital Brno, Brno, Czech Republic; ⁴Research Centre for Toxic Compounds in the Environment, Masaryk University, Brno, Czech Republic; ⁵Department of Infectious Diseases, University Hospital Brno, Brno, Czech Republic
Email: husa.petr2@fnbrno.cz

Background and aims: Selectins (cluster of differentiation, CD62) are a family of transmembrane glycoproteins expressed on the surface of different cells. E-selectin (ES) is primarily present in membranes of endothelial cells. Inflammatory cytokines like tumor necrosis factor alpha or interleukin 1 beta stimulate ES expression. ES binds with CD15 s on the surface of neutrophils, allowing reversible adhesion of leucocytes and their rolling movement on endothelial cells. By the described mechanism, ES plays a fundamental role at the beginning of the physiological inflammatory response. Elevated ES levels are associated with different diseases like atherosclerosis, rheumatoid arthritis, HIV, or chronic hepatitis C (CHC). Aim of the study was to assess ES concentrations in the group of patients with CHC in comparison with the control group (CG).

Method: A total of 36 patients with CHC treated with direct acting antivirals (DAA) was included in study group (SG). The control group consisted of 40 healthy individuals. ES levels were detected in venous blood using a conventional sandwich ELISA test-Human sE-selectin Platinum ELISA (eBioscience, San Diego, USA). Testing was performed at baseline (BS), at the end of antiviral treatment (ET) and 12 weeks after the last dose of DAA (SVR12). The Mann-Whitney U test was used for comparison of ES levels between two groups.

Results: The median of ES concentration in CG was 6.2 (1.6–13.3) ng/ml, in SG 76.7 (27.8–179.3) ng/ml at BS, 69.9 (21.7–167.4) ng/ml at ET and 57.8 (20.5–120.2) ng/ml at SVR12. The difference between CG and SG at BS, ET, and SVR 12 was statistically significant (p < 0.001). All patient with CHC achieved a sustained virological response.

Conclusion: ES concentrations were significantly higher in SG at BS and remained elevated at SVR12 although the decrease during the study was also substantial ($p < 0.001$ between BS and ET as well as between ET and SVR12). The basis of the increased concentration in SG is a systemic inflammatory reaction that persists even after achieving SVR.

SAT-423

Highly expressed CTLA4 on B cells defected BCR signal to inhibit the secretion of anti-HBs in CHB patients

Shengxia Yin¹, Xin Tong¹, Chao Wu¹, Jie Li¹. ¹Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China
Email: att717@163.com

Background and aims: The generation of anti-HBs is lacking in CHB patients. The cause is controversial. B cells activation state has a crucial effect on the secretion level of antibodies. Therefore, B cell status deserves more attention.

Method: Single-Cell RNA-seq analysis was performed in peripheral B cells. Peripheral and liver infiltrated B cells were characterized by flow cytometry. BCR signaling was tested by Ca⁺ flow and WB assay. Aimed to explore the inhibiting role of CTLA4, we did CTLA4-blocking test *in vitro*. Further, B6-Ighm-KO mice were injected with HBsAg preimmunized CTLA4^{-/-} B cell after establishing HBV transduction model and HBV serological indicators were detected. CO-IP assay and proteome analysis was made to explore the downstream proteins of CTLA4.

Results: CTLA4 was highly expressed in B cells of CHB patients and more obviously in HBsAg-specific B cells. Moreover, CTLA4 was highly expressed in about 50% of the infiltrating HBsAg-specific B cells. CTLA4+HBsAg+B cells tended to show activated markers. GO analysis, Ca⁺ flow and WB assay showed that BCR signaling of CTLA4+B cells was defected. Moreover, CTLA4 blocking could partly restore the deflection and make B cells secreted more anti-HBs. *n* mice model, B6-Ighm-KO mice injected with CTLA4^{-/-} B cells showed decreased level of HBV serological indicators. Proteome assay showed SHIP-1 was the down stream of CTLA4.

Conclusion: The circulating and liver infiltrating B cells increased the expression of CTLA4 to defected the BCR signal which might contribute to the deficiency of viral specific humoral response during CHB course.

WED-420

Evaluation of molnupiravir as an antiviral against hepatitis E virus infection

Siddharth Sridhar¹, Shusheng Wu¹, Jianwen Situ², Estie Hon-Kiu Shun², Nicholas Foo-Siong Chew². ¹Department of Microbiology, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong; ²Department of Microbiology, School of Clinical Medicine, LKS Faculty of Medicine, The University of Hong Kong, Hong Kong, Hong Kong
Email: sid8998@hku.hk

Background and aims: Hepatitis E virus (HEV) is an important cause of chronic hepatitis in immunocompromised persons. There are few effective treatment options for patients with chronic hepatitis E who are intolerant or unresponsive to ribavirin. Drug repurposing efforts are required to identify new treatment options for this condition. Molnupiravir is a prodrug of a broad-spectrum antiviral nucleoside

analogue (N-hydroxycytidine) that induces lethal mutagenesis in viral populations. This drug has recently been licensed globally for treatment of Coronavirus Disease 2019 (COVID-19). This study aimed to evaluate activity of molnupiravir against HEV.

Method: *In vitro* cytotoxicity and antiviral efficacy of varying concentrations of molnupiravir were assessed using infectious cDNA clones (pSK-HEV-2) and patient derived HEV isolates in Huh7 and PLC/PRF/5 cells respectively. Rats were immunosuppressed with a combination of prednisolone, tacrolimus, and mycophenolate mofetil administered by oral gavage. These are commonly used immunosuppressants in organ transplant recipients and are proven to prolong HEV infection in rats (Sridhar S et al, JHEP Reports, 2022). Immunosuppressed rats were infected with HEV for one week and then treated with molnupiravir (dosed at either 250 mg/kg/day or 400 mg/kg/day), ribavirin 50 mg/kg/day, or left untreated. Antiviral effectiveness in clearing HEV in serum, faeces, and liver tissue was compared to control and ribavirin-treated rats over 28 days. Liver histology and immunohistochemistry was assessed.

Results: Molnupiravir demonstrated low cytotoxicity and dose-dependent reduction in supernatant RNA load in both infectious cDNA clone and wildtype HEV cell culture models. In the animal model, untreated animals harbored prolonged HEV infection until end of experiment. The higher dose of molnupiravir (400 mg/kg/day) rapidly reduced viral shedding in serum and stool compared to other treatment groups. A majority of rats treated at the 400 mg/kg/day molnupiravir dose level cleared infection in both compartments by week 4 of treatment. Liver tissue showed improved histology and decreased immunohistochemical staining in the molnupiravir group together with lower viral loads at end of treatment.

Conclusion: Molnupiravir, a licensed antiviral for COVID-19, shows promise against HEV in *in vivo* and *in vitro* models. Further work is required to translate molnupiravir into a clinical solution for ribavirin-refractory chronic hepatitis E.

WED-421

Hepatitis E in Japan: a nationwide survey 2012–2017

Takeshi Matsui¹, Jong-Hon Kang², Kazunari Tanaka², Hiroaki Okamoto³. ¹Center for Gastroenterology, Teine-Keijinkai Hospital, Sapporo, Japan; ²Center for Gastroenterology, Teine Keijinkai Hospital, Sapporo, Japan; ³Jichi Medical University School of Medicine, Simotsuke, Japan
Email: mtake0402@gmail.com

Background and aims: In Japan, testing for hepatitis E virus (HEV) has been covered by the medical insurance system since November 2011. Since then, the diagnosis of HEV infection has rapidly expanded in clinical practice throughout the country. These changing circumstances have encouraged us to conduct a nationwide investigation of HEV infection.

Method: To 525 medical facilities, we requested a survey to investigate the medical record for the patients with HEV infection diagnosed from 2012 to 2017. The questionnaire included baseline characteristics, clinical course and virologic aspects of the patients.

Results: A total of 503 cases (407 males, average age of 56.6 years) were registered from 155 medical facilities across Japan. In Eastern Japan, 324 cases were collected from 69 facilities (4.7 cases/facility), and 179 cases were gathered from 86 (2.1 cases/facility) in Western Japan. Among them, 273 patients had habitual alcohol consumption of 30 g/day or more. Pre-existing liver disease was present in 93 patients, hypertension in 84, diabetes mellitus in 82, and dyslipidemia in 93, respectively. The average Body Mass Index (BMI) at onset was 23.9 kg/m². Except for four cases, none had traveled to HEV endemic areas. Ninety patients had consumed pork meat within the past two months, 87 had ingested pork offal, 13 had consumed venison, and 18 had eaten wild boar meat. Transfusion transmission of HEV was suspected in 4 patients. For the diagnosis of HEV infection, 468 (98.5%) of 475 patients underwent an anti-HEV IgA test, certified by insurance in Japan, and were positive. HEV RNA was

POSTER PRESENTATIONS

detected in 222 patients using PCR. Among 178 patients whose HEV genotypes were determined, genotype 3 was identified in 123 patients (69.1%), genotype 4 in 51 (28.7%), and genotype 1 in 4 (2.2%) patients who had traveled to endemic areas. Of the 503 patients, 346 (68.8%) were hospitalized, and 52 (10.3%) developed ALF. Six patients (1.2%) presented with hepatic coma, 2 (0.4%) received liver transplantation, and 4 (0.8%) died. ALF was associated with male gender, alcohol consumption, BMI, genotype 4, and pre-existing liver disease or diabetes. AHE shifted to chronic hepatitis in 6 patients (1.2%). They had undergone organ transplantation or had underlying diseases including hematological disorders, respectively. Extrahepatic manifestations such as neurological disorders including Guillain-Barré syndrome, were observed in six patients.

Conclusion: AHE in Japan was autochthonous with rare exceptions, and genotype 3 of HEV was the dominant strain. A higher incidence in Eastern Japan might be observed compared to the Western area. Whereas AHE was self-limited in almost 90% of patients, ALF developed in 10%, and 1% had a fatal course. This may be the first nationwide study to examine the clinical picture of HEV infection throughout Asian countries including Japan.

Email: ben.da@gilead.com

Background and aims: Hepatitis delta virus (HDV) causes the most severe form of viral hepatitis. While nucleos (t)ide analogues (NAs)

are first line treatments for chronic hepatitis B virus (HBV) infection, they have shown no impact on HDV RNA levels in chronic HDV (CHD) patients. Recent HDV guidelines recommend use of NAs in CHD patients with cirrhosis or those without cirrhosis and HBV DNA ≥ 2000 IU/ml. We evaluated virologic outcomes associated with bulevirtide (BLV) over 48 weeks when given with vs. without concomitant NAs.

Method: Data from 3 studies (MYR203, MYR204, MYR301) were pooled for participants receiving BLV 2 mg/d or 10 mg/d as monotherapy, or no anti-HDV treatment (MYR301 control arm). In MYR204 and MYR301, NA use was allowed based on HBV guidelines. HDV outcomes (virologic response [VR], defined as undetectable HDV RNA or $\geq 2 \log_{10}$ IU/ml decrease from baseline [BL], ALT normalization, and combined response [CR], defined as VR and ALT normalization), and HBV outcomes (% with undetectable HBV DNA, defined as $< \text{LLOQ}$ [10 IU/ml], target not detected), change from BL in HBV DNA and in HBsAg levels in participants with HBV DNA $\geq \text{LLOQ}$ at BL) were assessed over 48 weeks (W) in those receiving vs. not receiving NAs. **Results:** 280 participants were included in 4 groups: BLV 2 mg/d (n = 64), BLV 10 mg/d (n = 165), total BLV (n = 229), and no anti-HDV treatment (control; n = 51). Overall, NAs were used concomitantly in 160 participants (57%; group ranges: 48%–63%). BL characteristics were comparable except the proportion with cirrhosis and mean liver stiffness were higher (50% and 14.7 kPa) in those on NAs vs. no NAs (29% and 13.7 kPa). Tenofovir-based therapy was most used (87% [139/160]). For the total BLV group, CR, VR, and ALT normalization with vs. without NAs at W48 were: 45% vs. 47%, 83% vs. 73%, and 50% vs. 58%, respectively; these responses were 3% vs. 0%, 6% vs. 0%, and 9% vs. 16% for controls, respectively. Mean changes from BL in HBV DNA at W48 with and without NAs were -1.37 vs $-0.71 \log_{10}$ IU/ml for the total BLV group, and -0.81 vs $-0.15 \log_{10}$ IU/ml for control. For the total BLV group, 24% (30/126) and 36% (45/124) receiving concomitant NAs had undetectable HBV DNA at BL and W48, respectively, while 13% (13/100) and 21% (20/97) of participants not receiving concomitant NAs had undetectable HBV DNA at these times. For controls, 25% (8/32) and 41% (13/32) on NAs and 21% (4/19) and 11% (2/18) not on NAs had undetectable HBV DNA at BL and W48, respectively. BLV given with or without NAs had no impact on HBsAg levels.

Conclusion: NAs given with BLV for 48 weeks had no impact on HDV responses, while greater reductions in HBV DNA levels were seen when BLV and NAs are combined compared to BLV alone.

TOP-401-YI

Improvement of liver stiffness during nucleos (s)ide analogue treatment in patients with chronic hepatitis B and advanced fibrosis is not associated with a reduction in hepatocellular carcinoma risk

Lesley A. Patmore¹, Yan Liang², Mai Kilany³, Arno Furquim d'Almeida⁴, Vincent Wai-Sun Wong², Thomas Vanwolleghem⁴, Pieter Honkoop⁵, Hans Blokzijl⁶, Ozgur Koc⁷, Harry L.A. Janssen^{1,3}, Matthijs Kramer⁷, Joep de Bruijne⁸, A. Kaewdech⁹, Robert A. de Man¹, R. Bart Takkenberg¹⁰, Grace Lai-Hung Wong², Jordan J. Feld³, Milan J. Sonneveld¹. ¹Erasmus MC, University Medical Center, Rotterdam, Netherlands; ²The Chinese University of Hong Kong, Hong Kong, Hong Kong; ³Toronto Centre for Liver Disease, Toronto General Hospital, University of Toronto, Toronto, Canada; ⁴Antwerp University Hospital, University of Antwerp, Edegem, Belgium; ⁵Albert Schweitzer Hospital, Dordrecht, Netherlands; ⁶University Medical Center Groningen, University of Groningen, Groningen, Netherlands; ⁷Maastricht University Medical Center, Maastricht, Netherlands; ⁸University Medical Center Utrecht, University of Utrecht, Utrecht, Netherlands; ⁹Prince of Songkla University, Songkhla, Thailand; ¹⁰Amsterdam University Medical Centers, Amsterdam, Netherlands
Email: l.patmore@erasmusmc.nl

Background and aims: Chronic hepatitis B (CHB) patients with advanced fibrosis are at high risk for hepatocellular carcinoma (HCC)

and other adverse liver outcomes. Since liver stiffness correlates with severity of fibrosis in untreated patients, an improvement in liver stiffness measurement (LSM) by vibration-controlled transient elastography is used as a surrogate marker for fibrosis regression in patients on antiviral therapy. However, the association between on-treatment LSM with adverse liver-related outcomes is yet unknown. **Method:** We conducted an international multicenter retrospective cohort study of mono-infected CHB patients with advanced fibrosis ($\geq F3$ based on liver biopsy or LSM ≥ 9.0 kPa) and with available on-treatment LSM after at least 3 years of follow-up, at sites in Belgium, Canada, Hong Kong, the Netherlands, and Thailand. On-treatment LSM was categorized into <6 kPa, 6–9 kPa and >9 kPa. We assessed the association between on-treatment LSM with HCC development, as well as liver-related events (first of HCC, liver transplantation and liver-related mortality).

Results: We analyzed 512 patients with a median age at baseline of 50 years, 76% were male. Median baseline HBV DNA was 5.6 log₁₀ IU/ml. At baseline 40.8% had F3 and 59.2% had F4, 71.7% was based on LSM (median 12.7 kPa, IQR 10.5–17.6). All patients initiated antiviral therapy with nucleos(t)ide analogue and 93% had undetectable HBV DNA at on-treatment LSM. The median time between baseline assessment and on-treatment LSM was 4.5 years and median on-treatment LSM was 6.9 kPa (IQR 5.1–10.3). The on-treatment LSM was <6 kPa in 196 (38.3%) patients, 6–9 kPa in 156 (30.5%) patients and >9 kPa in 160 (31.2%) patients. During a median follow-up of 6.8 years after the on-treatment LSM, 53 patients developed HCC. In univariable analysis, on-treatment LSM was not associated with HCC development (hazard ratio [HR] 1.01, $p = 0.607$). The 5-year cumulative HCC incidence was comparable across on-treatment LSM strata; 4.7% for <6 kPa, 6.2% for 6–9 kPa and 4.3% for >9 kPa ($p = 0.454$). In multivariable analysis adjusting for age, sex, platelet count, ALT and HBV DNA, only older age (adjusted HR [aHR] 1.056, $p < 0.001$) and platelet count (aHR 0.992, $p = 0.011$) were significantly associated with HCC development, whereas on-treatment LSM was not (aHR 1.027, $p = 0.833$). Findings were consistent for patients with F3 ($p = 0.512$) or F4 at baseline ($p = 0.249$). The risk of liver-related events was also comparable across LSM strata (4.7% for <6 kPa, 6.2% for 6–9 kPa and 5.9% for >9 kPa ($p = 0.184$)).

Conclusion: The majority of CHB patients with advanced fibrosis decreases in LSM during antiviral therapy. Unfortunately, this improvement is not associated with a clinically relevant reduction in the risk of HCC and liver-related events. On-treatment LSM should therefore not be used to guide HCC surveillance strategies, nor as a surrogate end point in clinical trials.

Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; ¹⁰German Center for Infection Research (DZIF), HepNet Study-House/German Liver Foundation, Hannover, Germany; ¹¹Centre for Individualized Infection Medicine (CiiM), Helmholtz Centre for Infection Research/Hannover Medical School, Hannover, Germany; ¹²Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany Email: sandmann.lisa@mh-hannover.de

Background and aims: Infection with the hepatitis D virus (HDV) can lead to hepatitis delta, which is associated with a high risk of developing liver-related complications, including hepatic decompensation and hepatocellular carcinoma (HCC). The global epidemiology and disease severity of hepatitis delta is highly heterogeneous and disease presentation has changed over the last decades. There is limited knowledge on disease pathophysiology and host-virus interactions explaining the large inter-individual variability in the course of the disease. We aim to screen a large multicentre cohort of well-defined HDV-infected patients from different European countries to better understand not only the epidemiology but also to identify individual factors that determine the outcome of infection, thus providing the basis for an individualised treatment approach.

Method: We report first findings from an observational, non-interventional, cross-sectional multicentre cohort with the aim of enrolling 1000 European HDV-infected patients from England, France, Italy, Germany, Romania and Sweden. Patients with detectable anti-HDV for at least 6 months can be included. Retrospective data is obtained from databases and patient records for each patient's most recent visit that is eligible for inclusion (index visit). Available biosamples are used for virological and immunological analyses.

Results: To date, 561 patients have been included (England 27%, Italy 9%, Germany 19%, Romania 11%, Sweden 34%). The majority of patients is male (55%) with a mean age of 48 ± 12 years. The top three countries of birth were Romania (17%), Mongolia (15%) and Sierra Leone (8%). Two out of five patients were classified as having cirrhosis at the index visit (39%, 216/560), of whom 14% (29/211) and 31% (65/207) presented with ascites or esophageal varices while only few patients had signs of hepatic encephalopathy (4%, 9/211). A history of previous hepatic decompensation was documented in 11% (57/518) of patients. HCC was reported for only 29 patients (5%) at the index visit. Regarding antiviral treatment, 40% (223/560) of patients had a history of interferon (IFN)-based treatment, while only 3% were receiving IFN-based treatment at the index visit. Nucleos(t)ide analogues were used in 53% of patients and bulevirtide (BLV) in 6% (34/561). The latter is likely to underestimate the number of patients actually treated with BLV, as patients included in other registries and/or clinical trials were excluded. Anti-HCV antibodies were present in 8% of cases, while HCV RNA was not detected in any of the patients. HDV RNA was detected in 47% of patients, respectively.

Conclusion: This study has the potential to elucidate HDV epidemiology, disease burden and cascades of HDV care in a large multicentre cohort. Data collection is still ongoing and the results from the updated dataset will be presented at the conference.

Background and aims: Prediction of hepatitis B surface antigen (HBsAg) seroclearance in individuals with chronic hepatitis B (CHB) is challenging but crucial for understanding outcomes of infection and to support the evaluation of novel therapies aiming at functional cure. **Method:** We studied a large ethnically diverse cohort of CHB adults (on or off antiviral treatment) from 7 secondary care centres in England with longitudinal laboratory and clinical monitoring, established by the National Institute for Health and Care Research Health Informatics Collaborative (NIHR HIC) from electronic health records (EHRs), representing data between 1992–2022. HBsAg seroclearance was determined by a negative HBsAg test, confirmed by at least one follow-up negative. Follow-up duration was defined as the interval between the date of CHB diagnosis and the date of HBsAg seroclearance or last HBsAg measurement. We excluded individuals with followed up duration <6 months, or liver transplantation. We conducted univariate analyses to explore the characteristics of individuals with vs without HBsAg seroclearance. Data were randomly split into training and test sets (90% vs 10%). We applied 10 machine learning (ML) models for HBsAg seroclearance prediction based on the most predictive variables selected by univariate analyses. We derived the relative feature importance based on the ML models of best performance, evaluated by area under the receiver operating characteristics curve (AUC).

Results: We included 4,448 adults who were followed up for 21,589 person years (median follow-up of 4 years per patient). 55% were male, and the median age was 39 (interquartile range (IQR): 32–49) years, 37% on treatment, comprising 37% Asian, 21% Black, 29% White, and 13% other ethnicities. 304 patients (1.4%) achieved HBsAg

seroclearance (226 confirmed with a follow-up result, 1.0%), On univariate analysis, individuals who were older at baseline, male, of White ethnicity, untreated, and had lower baseline HBV viral load (VL) and HBsAg, higher alkaline phosphatase (ALP), lower haemoglobin (Hb), HCV/HBV coinfection, and longer follow-up, were more likely to have HBsAg seroclearance (all $p < 0.05$). The five best predictive ML models (AUC ≥ 0.80) confirmed that baseline age, ethnicity, follow-up duration, baseline HBV VL, ALP, Hb, bilirubin, deprivation score, treatment status, and creatinine, are consistently the top 10 important factors contributing to the prediction performance.

Conclusion: In addition to well-known predictors, we identified ethnicity, deprivation score, and several routine laboratory parameters for HBsAg seroclearance prediction. Big data analytics and ML by utilising large EHRs datasets can be promising to identify individuals with the highest chance of HBsAg loss which is relevant to determining immune-mediated clearance and functional cure using new therapeutic agents.

Burden of liver disease progression in patients with chronic HDV infection: a population-based study for France

Lucia Parlati¹, Charlotte Mouliade², Samir Bouam³, Philippe Sogni², Stanislas Pol², Vincent Mallet². ¹AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France, Université Paris Cité, F-75006, Paris, France, Paris, France; ²AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, DMU Cancérologie et spécialités médico-chirurgicales, Service des Maladies du foie, Paris, France, Université Paris Cité, F-75006, Paris, France, Paris, France; ³AP-HP.Centre Université de Paris, Groupe Hospitalier Cochin Port Royal, DMU PRIM, Service d'Information Médicale, Paris, France
Email: lucia.parlatti85@gmail.com

Background and aims: The burden of liver disease progression to hepatocellular carcinoma or decompensated cirrhosis associated with chronic hepatitis D virus (HDV) infection remains largely unquantified at the population level.

Method: We conducted a retrospective analysis using data from the French National Diagnosis Related Group Database (2014–2023), focusing on cases of chronic HDV infection (ICD-10 code B180) recorded in French hospitals over the past decade. Our objective was to estimate the Population Attributable Fraction (PAF) of alcohol use disorders, non-HDV related chronic liver diseases, type-2 diabetes mellitus, and obesity, in relation to the risk of liver disease progression. We used logistic regression models adjusted for sex, age at censoring, deprivation and major comorbidities, to compute the probability of liver disease progression under both actual conditions and counterfactual scenarios—the latter representing a hypothetical absence of specific risk factors. The PAFs were determined by comparing these probabilities to quantify the contribution of each risk factor to liver disease progression.

Results: Of 5,954 individuals (median [IQR] age at inception 48 [36–61] years, 54% men), 14% ($n = 832$) were recorded with liver disease progression (7.2% with hepatocellular carcinoma, 10.5% with decompensated cirrhosis). The median age at the time of liver disease progression was 54 (44–62) years, with an overwhelmingly (76%) male predominance. Among patients with liver disease progression, the prevalence of alcohol use disorders, non-HDV related chronic liver diseases, obesity, and type-2 diabetes mellitus was 41.6%, 28.8%, and 37%, respectively. Key risk factors of liver disease progression ($p < 0.01$) were male sex [aOR 2.2 (95% CI: 1.82 to 2.67)], alcohol use disorders [aOR 4.97 (4.09 to 6.04)], non-HDV related chronic liver diseases [aOR 5.37 (3.73 to 7.70)], type-2 diabetes mellitus [aOR 1.57

(1.23 to 1.99), and obesity [1.47 (1.16 to 1.86)]. Severe comorbidities [aOR 0.42 (0.33 to 0.53)], and deprivation [aOR 0.84 (0.71 to 1.00)] were not association with liver disease progression. The PAF (95% CI) for alcohol use disorders, type-2 diabetes mellitus, non-HDV related chronic liver diseases, and obesity were 28.1% (26.7%–29.4%), 6.4% (6.0%–6.8%), 5.5% (4.6%–6.3%), and 5.4% (5.1%–5.7%), respectively.

Conclusion: Approximately 45% of the liver disease burden linked to chronic HDV infection in France from 2014 to 2023 was found to be attributable to modifiable, non-HDV-related risk factors.

FRI-362-YI

Hepatitis B surface antigen (HBsAg) seroclearance following discontinuation of nucleos (t)ide analogues (NA) treatment has comparable durability to HBsAg seroclearance achieved during NA therapy

Terry Cheuk-Fung Yip^{1,2,3}, Mandy Sze-Man Lai^{1,2}, Jimmy Che-To Lai^{1,2,3}, Yee-Kit Tse^{1,2,3}, Henry L.Y. Chan^{2,4}, Vincent Wai-Sun Wong^{1,2,3}, Grace Lai-Hung Wong^{1,2,3}. ¹Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong; ²Medical Data Analytics Centre (MDAC), The Chinese University of Hong Kong, Hong Kong, Hong Kong; ³Institute of Digestive Disease, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong, Hong Kong; ⁴Department of Internal Medicine, Union Hospital, Hong Kong, Hong Kong
Email: tcfyip@cuhk.edu.hk

Background and aims: The durability of hepatitis B surface antigen (HBsAg) seroclearance achieved after nucleos (t)ide analogues (NA) therapy cessation is not well defined. We compared the cumulative rate of HBsAg seroreversion and seroconversion in patients who developed HBsAg loss after stopping NA, during NA therapy, after interferon (IFN) treatment, or spontaneously.

Method: Adult patients with chronic hepatitis B mono-infection who cleared HBsAg from 2000–2022 were identified from a territory-wide database in Hong Kong. Patients with liver transplantation, cancer, or use of immunosuppressants before HBsAg loss were excluded. Time-dependent cause-specific hazard (CSH) models were used to compare different forms of HBsAg loss on the development of HBsAg seroreversion and seroconversion and examine the factors linked to these outcomes.

Results: Of 6, 028 patients with HBsAg loss (mean age 58 ± 13 years; 38.6% female; 3.8% cirrhosis), 259 (4.3%), 865 (14.3%), 100 (1.7%), and 4, 804 (79.7%) lost HBsAg after NA therapy cessation, during NA therapy, after IFN treatment, and spontaneously respectively; their corresponding mean age at HBsAg loss was 54, 56, 50, and 58 years; 30.1%, 28.3%, 23.0%, and 41.3% were female respectively. Most patients had normal liver function at HBsAg loss. In patients who cleared HBsAg after NA therapy cessation, during NA therapy, after IFN treatment, and spontaneously, 9 (3.5%), 51 (5.9%), 4 (4.0%), and 261 (5.4%) developed HBsAg seroreversion at a median (25th–75th percentile) follow-up of 4.9 (2.5–8.3) years. The 10-year overall cumulative risk (95%CI) of HBsAg seroreversion was 9.6% (7.8%–11.6%). Compared to patients with HBsAg loss during NA therapy, those with HBsAg loss after NA therapy cessation (adjusted CSH ratio [aCSHR] [95%CI] 0.58 [0.29–1.19], *p* = 0.14), after IFN treatment (0.65 [0.23–1.81], *p* = 0.41), or spontaneously (0.81 [0.59–1.10], *p* = 0.18) had a comparable rate of HBsAg seroreversion. Male gender (aCSHR [95%CI] 0.76 [0.61–0.95]) and positive anti-HBs (0.44 [0.30–0.64]) were associated with a lower rate of HBsAg seroreversion, while diagnosis of cancer (3.03 [1.89–4.84]) and immunosuppressant use (1.79 [1.17–2.74]) during follow-up were associated with more HBsAg seroreversion. Among 3, 449 patients with antibody to HBsAg (anti-HBs) measurement, the 10-year cumulative incidence (95%CI) of positive anti-HBs was 53.6% (51.7%–55.5%). Patients who achieved HBsAg loss after NA therapy cessation (aCSHR [95%CI] 1.00 [0.77–1.29]), after IFN treatment (1.19 [0.86–1.65]), or spontaneously (0.98 [0.86–1.13]) had a similar rate of developing positive anti-HBs compared to those with HBsAg loss during NA therapy.

Conclusion: HBsAg seroclearance achieved after NA therapy cessation is similarly durable to those achieved during NA therapy, after IFN treatment, and spontaneously, with a comparable chance of HBsAg seroconversion over time.

FRI-363-YI

Association between metabolic dysfunction, severity of liver fibrosis and fibrosis progression in patients with chronic hepatitis B-an individual patient data meta-analysis

Lisa M. van Velsen¹, Lesley A. Patmore¹, Jordan J. Feld², Henry L.Y. Chan³, Teerha Piratvisuth⁴, Rong-Nan Chien⁵, Edo J. Dongelmans¹, Vedran Pavlovic⁶, Leland J. Yee⁷, Willem Pieter Brouwer¹, Audrey H. Lau⁷, Bettina E. Hansen¹, Maria Buti^{8,9}, Qing Xie¹⁰, Keyur Patel², Scott K. Fung², Harry L.A. Janssen^{1,2}, Milan J. Sonneveld¹. ¹Erasmus University Medical Center, Rotterdam, Netherlands; ²Toronto Centre for Liver Disease, University of Toronto, Toronto, Canada; ³The Chinese University of Hong Kong, Hong Kong, China; ⁴Prince of Songkla University, Hat Yai, Thailand; ⁵Chang Gung Memorial Hospital, Linkou Branch, Taiwan, College of Medicine, Chang Gung University, Taiwan, Taipei, Taiwan; ⁶Roche Products Ltd, Welwyn Garden City, United Kingdom; ⁷Gilead Sciences, Foster City, United States; ⁸Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; ⁹CIBER Hepatic and Digestive Diseases (CIBERehd), Instituto Carlos III, Madrid, Spain; ¹⁰Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China
Email: l.vanvelsen@erasmusmc.nl

Background and aims: Presence of metabolic comorbidities (ie. overweight, diabetes mellitus [DM], hypertension [HT], and dyslipidemia [DL]) has been associated with a higher risk of liver-related outcomes in chronic hepatitis B (CHB) patients. We studied the association between presence of metabolic comorbidities with severity of liver fibrosis before and during antiviral therapy (AVT).

Method: We analyzed data from the SONIC-B database, which comprises data of CHB patients who underwent liver biopsy in two tertiary clinics in the Netherlands and Canada, or as part of 8 global clinical trials. We analyzed the association between the presence of metabolic comorbidities with severity of liver fibrosis in currently untreated patients, and with fibrosis regression (decrease of ≥1 METAVIR class in patients with baseline METAVIR ≥F2) and fibrosis progression (increase from METAVIR F0–2 at baseline to METAVIR F3–4) in biopsies taken at 48–72 weeks after initiation of AVT. Comparisons were performed using the Chi-square test and multi-variable logistic regression.

Results: We analysed biopsies from 2821 currently untreated CHB patients. Median age was 37 years, 53% HBeAg positive, with median HBV DNA of 7.17 log IU/ml. Overweight, HT, DM and DL were present in 51%, 6.8%, 4.3% and 3.9% of patients, and 25.4% had advanced fibrosis (METAVIR F3–4). Presence of overweight (30.8 vs 19.8%; *p* < 0.001), HT (39.3 vs 24.4%, *p* < 0.001), DM (42.5 vs 24.7%, *p* < 0.001) and DL (46.8 vs 24.6%, *p* < 0.001) was associated with a higher risk of advanced fibrosis. The highest risk of advanced fibrosis was seen in patients with multiple comorbidities (19.4% if no metabolic comorbidities, 27.9% with 1 comorbidity, 43.6% if ≥2 comorbidities, *p* < 0.001). Findings were consistent in multivariable analysis (adjusted odds ratio [aOR] for 1 comorbidity: 1.135, aOR for ≥2 comorbidities: 1.566, *p* = 0.022). Follow-up biopsy was available for 1307 patients, 757 treated with NUC monotherapy and 550 with PEG-IFN ± NUC. Fibrosis regression was observed in 261 (39.4%) patients, and was more often observed in patients without metabolic comorbidities (49.8%), when compared to patients with 1 (33.9%) or ≥2 metabolic comorbidities (28.0%, *p* < 0.001). Findings were consistent in multivariable analysis (aOR for 1 comorbidity: 0.646, aOR for ≥2 comorbidities: 0.463, *p* = 0.020). Finally, progression to advanced fibrosis during AVT was predominantly seen in patients with metabolic comorbidities: the risk was 4.6% in patients without metabolic comorbidities, compared to 9.8% and 14.3% in patients with 1 or ≥2 metabolic comorbidities (*p* = 0.001).

POSTER PRESENTATIONS

Conclusion: Presence of metabolic comorbidities in untreated patients with CHB is associated with more severe liver fibrosis. Furthermore, in patients on AVT, presence of metabolic comorbidities is associated with less fibrosis regression, and even a significant risk of fibrosis progression.

FRI-364

Baseline and reduction at 1 year of hepatitis B surface antigen level predicts functional cure and low HBsAg titer: A long-term kinetics of hepatitis B surface antigen

Soon Kyu Lee¹, Jung Hyun Kwon¹, Soon Woo Nam¹. ¹Division of Hepatology, Department of Internal Medicine, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Rep. of South
Email: doctorkwon@catholic.ac.kr

Background and aims: Long-term nucleos(t)ide analogue (NA) therapy is usually mandatory in patients with chronic hepatitis B (CHB) infection. In the stopping rule, a low HBsAg titer (<2 log IU/ml) has been suggested as the cut-off level for stopping NA therapy. However, the long-term kinetics of quantitative HBsAg levels and their predictive role in functional cure or stopping NA strategy remain unclear.

Method: We consecutively enrolled 1661 patients with chronic hepatitis or liver cirrhosis who started NA therapy between 2006 and 2020. Finally, 852 patients (entecavir, n = 287; tenofovir, n = 565), who were serially checked annually for HBsAg levels, were analyzed in our study. Patients were classified into three groups according to the quantitative HBsAg levels: the low HBsAg group (HBsAg <2 log IU/ml), the intermediate HBsAg group (2 log ≤ HBsAg <3 log IU/ml), and the high HBsAg group (HBsAg ≥ 3 log IU/ml). The primary outcome was the identification of the rate and predictive factors of functional cure and achievement of low HBsAg titer during NA treatment. Moreover, we also evaluated the long-term kinetics of HBsAg levels and the development of hepatocellular carcinoma (HCC).

Results: During a mean follow-up of 6.3 ± 3.6 years, the rate of functional cure after NA treatments was 2.28% (n = 19), and 108 patients (12.9%) achieved a low HBsAg group. The rate of the low HBsAg and intermediate group increase from 6.5% and 15.3% at baseline to 7.7% and 17.9% at the first year, and 14.2% and 39.6% at 8 years, respectively. The changes in the mean levels of HBsAg showed a steep reduction in the first year of NA therapy than after the first year in both functional and non-functional cure groups. The HBeAg (+) group demonstrated a higher baseline HBsAg titer and a greater reduction at one year compared to the HBeAg (-) group. Among patients with HBeAg (+), the chronic hepatitis group showed a significant reduction at one year. In multivariate Cox-regression analysis, lower baseline HBsAg titer (<1000 IU/ml), and the presence of reduction in the 1 year of HBsAg titer were both identified as predictive factors for an achievement of functional cure and low HBsAg titer after NA therapy. During follow-up, there was no development of HCC in patients achieving functional cure.

Conclusion: Our study demonstrated the rapid reduction in HBsAg titer in the first year of NA therapy and an increase in low HBsAg group during NA therapy. Moreover, lower baseline HBsAg titer and a decrease in the first year of HBsAg titer may predict functional cure and low HBsAg titer during NA treatments.

FRI-365-YI

Limited use of established risk scores for the prediction of hepatocellular carcinoma in patients with chronic hepatitis B virus infection

Robin Iker^{1,2}, Anika Wranke^{1,2}, Hannah Schneider¹, Heiner Wedemeyer^{1,2,3,4}, Helenie Kefalakes^{1,2,3,4}, Lisa Sandmann^{1,3,4}. ¹Department of Gastroenterology, Hepatology, Infectious Diseases and Endocrinology, Hannover Medical School, Hannover, Germany; ²German

Center for Infection Research (DZIF), Hannover/Braunschweig, Hannover, Germany; ³D-SOLVE: EU-funded Network on individualized management of hepatitis D, Hannover, Germany; ⁴Excellence Cluster RESIST, Excellence Initiative Hannover Medical School, Hannover, Germany
Email: iker.robin@mh-hannover.de

Background and aims: Hepatocellular carcinoma (HCC) is a major health burden and one of the leading causes of cancer-related deaths worldwide. Patients with chronic HDV infection (CHD) are at risk of developing HCC. In chronic HBV or HCV infection, risk scores are commonly used to predict HCC, but none has been validated in CHD. Here, we aim to validate existing HCC risk scores for their predictive potential in patients with CHD.

Method: Data from patients with CHD and a minimum follow-up (FU) of 6 months were retrospectively collected at Hannover Medical School from 1990 to 2023. Patients with HCC development (CHD-HCC) during FU were identified and matched to patients without HCC development (CHD-non-HCC) based on sex, age, INR, and bilirubin in a 1:2 ratio. Time points for data collection were first visit to the clinic (BL), 12 (HCC-12) and 6 months (HCC-6) prior to HCC development, as well as at HCC diagnosis (HCC). Comparable time points were selected for the matched CHD-non-HCC cohort with the last one defined as the last available visit. Validated HCC risk scores were calculated and compared between the cohorts. The following scores were analyzed: PAGE-B (platelets, age, sex), aMAP (age, sex, albumin/bilirubin, platelets), Toronto HCC Risk Index (age, etiology, sex, platelets), REAL-B (age, sex, alcohol, cirrhosis, diabetes, platelets, alpha-fetoprotein (AFP)), CAMD (cirrhosis, age, sex, diabetes), AASL (age, albumin, sex, cirrhosis) and ADRES-HCC (sex, FIB-4 index, AFP).

Results: We retrospectively identified 251 CHD patients of whom 14% (36/251) were diagnosed with HCC during FU. At BL, the majority of CHD-HCC patients were male (75%), cirrhosis was present in 89% of patients and median time to HCC diagnosis was 3.42 years (IQR 1.4–6.96). The prevalence of liver cirrhosis, hepatic comorbidities and prior interferon treatment was similar to the matched 72 CHD-non-HCC patients. When comparing HCC prediction scores between the cohorts, overall test performance was poor. At BL, the REAL-B score reached the highest AUC with 0.655, followed by CAMD (AUC = 0.61) and aMAP (AUC = 0.61). Slightly weaker test performance was detected at HCC-12, with the three best performing tests being REAL-B (0.61), CAMD (AUC = 0.59) and ADRES-HCC (AUC = 0.56). At HCC-6, ADRES-HCC (AUC = 0.69), REAL-B (AUC = 0.66) and aMAP (AUC = 0.62) performed best. At HCC diagnosis, ADRES-HCC (AUC = 0.68) and aMAP (AUC = 0.66) were the two best scores to distinguish between patients with and without HCC. Interestingly, AFP alone outperformed all scores at every time point with an AUC of 0.69, 0.64, 0.75, and 0.78 at BL, HCC-12, HCC-6 and HCC respectively.

Conclusion: In our cohort, none of the analyzed scores predicted HCC development with sufficient accuracy and consistency. However, HCC risk stratification is essential for the management of CHD patients. Thus, the development of a valid HCC risk score should be addressed in future studies.

FRI-366

HBV DNA thresholds and immune tolerance: unveiling new insights from cross-sectional hepatic histology data in hepatitis B

Xiaoke Li¹, Tingyu Zhang², Xin Sun², Daqiao Zhou³, Xiaoling Chi⁴, Yueqiu Gao⁵, Yong-an Ye¹. ¹Dongzhimen Hospital, Beijing University of Chinese Medicine, Beijing, China; ²Beijing University of Chinese Medicine, Beijing, China; ³Shenzhen Traditional Chinese Medicine Hospital, Shenzhen, China; ⁴The Second Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China; ⁵Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, China
Email: lixiaoke@bucm.edu.cn

Background and aims: Immune tolerance (IT) is pivotal in HBV persistence. Current guidelines, constrained by liver biopsy

limitations, use high HBV viral loads and normal liver enzymes as surrogate IT markers. Yet, defining 'high viral load' lacks uniformity across regional guidelines. Furthermore, the definition of a quasi-immune tolerance phase in HBeAg-negative patients remains a contentious issue. This cross-sectional study in China seeks to clarify the relationship between serum HBV DNA levels and hepatic inflammation grades (from liver biopsy) in untreated chronic hepatitis B patients. It aims to uncover high viral load patterns with concurrent low hepatic inflammation in various infection statuses and to determine a more accurate HBV DNA threshold for IT identification.

Method: Our study encompassed 1,275 nucleos(t)ide analogue-naïve chronic HBV patients from China, including 568 HBeAg-negative and 707 HBeAg-positive subjects. The cohort was stratified based on HBeAg status, following which we delved into the relationship between hepatic inflammation (assessed through biopsy) and serum HBV DNA levels. Spearman's correlation analysis and a stepwise looping algorithm were employed for the precise determination of optimal HBV DNA cut-off values for assessing hepatic inflammation.

Results: The study identified distinct correlations within groups defined by HBV DNA thresholds. In HBeAg-negative patients, a threshold of 6.45 log₁₀ IU/ml was set, showing Spearman correlation coefficients of 0.40 ($p < 0.01$) and -0.32 ($p = 0.036$) below and above this level, respectively. In HBeAg-positive patients, an 8.92 log₁₀ IU/ml threshold resulted in coefficients of -0.10 ($p < 0.01$) and -0.63 ($p < 0.01$). These findings suggest a nuanced, non-linear connection between viral load and liver inflammation in both HBeAg-defined categories, with variable patterns across HBV DNA levels.

Conclusion: This study highlights the diverse relationship between HBV DNA viral load and hepatic inflammation in chronic hepatitis B patients at different DNA levels. Generally, elevated HBV DNA levels correlate with increased liver inflammation, but this trend reverses at higher levels. Interestingly, similar patterns are observed in both HBeAg-positive and -negative groups, albeit with lower HBV DNA thresholds in the latter. These findings challenge the traditional view that immune tolerance is exclusive to HBeAg-positive individuals, introducing the possibility of a quasi-immune tolerance state in HBeAg-negative patients. This revelation suggests a possible shift in our understanding of immune tolerance in chronic hepatitis B and underscores the need for a reevaluation of treatment strategies for these patients, potentially impacting their clinical management.

Prediction of hepatocellular carcinoma risk and liver-related events in chronic hepatitis D, an international retrospective cohort study (RIDE)

Lesley A. Patmore¹, Michelle Spaan¹, Kosh Agarwal², Ozgur Koc³, Hans Blokzijl⁴, Samantha Brouwer⁵, Hanneke van Soest⁶, Astrid van Hulzen⁷, Harry L.A. Janssen¹, Jolanda Lammers⁷, Louis Jansen⁸, Mark Claassen⁹, Robert A. de Man¹, R. Bart Takkenberg¹⁰, Remco van Dijk¹¹, Dirk Posthouwer³, Jurriën Reijnders^{1,5}, Ivana Carey², Milan J. Sonneveld¹. ¹Erasmus MC, University Medical Center, Rotterdam, Netherlands; ²King's College Hospital, London, United Kingdom; ³Maastricht University Medical Center, Maastricht, Netherlands; ⁴University Medical Center Groningen, University of Groningen, Groningen, Netherlands; ⁵Haga Hospital, The Hague, Netherlands; ⁶Haaglanden Medical Center, The Hague, Netherlands; ⁷Isala Hospital, Zwolle, Netherlands; ⁸OLVG, Amsterdam, Netherlands; ⁹Rijnstate Hospital, Arnhem, Netherlands; ¹⁰Amsterdam University Medical Centers, Amsterdam, Netherlands; ¹¹Leiden University Medical Center, Leiden, Netherlands
Email: l.patmore@erasmusmc.nl

Background and aims: Chronic hepatitis D (CHD) is the most severe form of chronic viral hepatitis, with a high risk of developing hepatocellular carcinoma (HCC) and other liver-related events. Risk

stratification is urgently needed to guide HCC surveillance strategies and to prioritize treatment with novel antiviral agents.

Method: We conducted a multicenter retrospective cohort of all consecutive anti-HDV positive patients managed at 10 academic and non-academic sites in the Netherlands and the United Kingdom. We excluded patients with current or past hepatitis C or HIV infection. The PAGE-B score was calculated at first visit as previously published based on platelet count, age and sex, and patients were categorized as low (<10), intermediate (10–17) and high risk (>17) for HCC development. We studied the cumulative incidence of HCC and liver-related events, defined as the first of a composite of HCC, liver transplantation and liver-related mortality, in the overall study population, and across PAGE-B risk strata.

Results: We analyzed 269 patients; 58% was male with a median age of 38 years (inter quartile range [IQR] 32–47) at enrolment. At enrolment, 35.5% had cirrhosis and 45% were HDV RNA positive. In 66.5% of patients antiviral therapy was started with either a nucleos(t)ide analogue (n = 164) and/or (pegylated) interferon (n = 41) during follow-up. During a median follow-up of 4.3 years (IQR 1.5–6.4), a total of 47 first events were recorded (HCC: n = 13, liver transplantation: n = 34, liver-related death: n = 13). The 5-year cumulative incidence of HCC and liver-related events were 3.8% (95% confidence interval [CI] 1.05–6.5), and 15.6% (95% CI 10.5–20.7). The 5-year cumulative incidence of HCC was 0% among patients with a low PAGE-B score (n = 115, 44% of cohort), compared to 3.2% in the intermediate risk group (n = 121, 46% of cohort) and 25.4% in the high risk group (n = 26, 10% of cohort; $p < 0.001$). The 5-year cumulative incidence of liver-related events was 2.1% among patients with a low PAGE-B score, compared to 21.1% in the intermediate risk group and 45.5% in the high risk group ($p < 0.001$). Findings were consistent in patients with cirrhosis at baseline; the 5-year cumulative HCC incidence was 0% in the low PAGE-B group, and 9.1% and 32.4% in the intermediate and high risk groups ($p < 0.001$). Among HDV RNA positive patients, the 5-year cumulative HCC incidence was 0% in the low PAGE-B group compared to 6.8% and 32.5% in the intermediate and high risk groups ($p < 0.001$).

Conclusion: Patients with CHD are at high risk of adverse liver-related outcomes. PAGE-B predicts the risk of HCC development and other liver related events, and can therefore be used to guide HCC surveillance strategies and treatment prioritization.

FRI-370

Bulevirtide efficacy and safety in chronic hepatitis delta patients on liver transplant waiting list

Magdalena Meszaros¹, Marie-Noëlle Hilleret^{2,2}, Jérôme Dumortier³, Louis Dalteroche⁴, Armand Abergel⁵, Marianne Latournerie⁶, Teresa Antonini⁷, Filomena Conti⁸, Patrick Borentain⁹, Nassim Kamar¹⁰, Camille Besch¹¹, Claire Francoz¹², Maryline Debette-Gratien¹³, Sébastien Dharancy¹⁴, Georges-Philippe Pageaux¹. ¹CHU Montpellier, Montpellier, France; ²CHU Grenoble Alpes, Grenoble, France; ³Hopital Edouard Erriot, Lyon, France; ⁴CHU Tours, Tours, France; ⁵CHU de Clermont-Ferrand, Clermont-Ferrand, France; ⁶CHU Dijon, Dijon, France; ⁷Hopital de la Croix Rousse, Lyon, France; ⁸APHP, Paris, France; ⁹CHU Timone, Marseille, France; ¹⁰CHU Toulouse, Toulouse, France; ¹¹CHU Strasbourg, Strasbourg, France; ¹²Beaujon Hospital, Clichy, University Paris Cité, Clichy, France; ¹³CHU dupuytren, Limoges, France; ¹⁴CHRU Lille, Lille, France
Email: m-meszaros@chu-montpellier.fr

Background and aims: Bulevirtide (BLV), a breakthrough antiviral inhibiting hepatitis Delta virus (HDV) cell entry, received European Medicine Agency approval in 2020 for HDV chronic infection in compensated liver disease patients. Its use in patients on liver transplant (LT) waiting list (for decompensated liver disease or hepatocarcinoma (HCC) remains underexplored. This study aims to gather real-life data on BLV usage in patients awaiting LT or undergoing LT candidacy evaluation.

POSTER PRESENTATIONS

Method: Consecutive HDV-infected cirrhotic patients being on liver transplant waiting list or undergoing pretransplant evaluation in whom BLV (2 mg daily) was prescribed were included.

Clinical, biological, and virological characteristics were collected at baseline, week 24 and week 48, and at LT. Liver-related events (HCC, LT) and adverse events were documented. Virological response was defined by HDV RNA undetectable or ≥ 2 -log decline vs. baseline, virologic non-response: HDV-RNA decline < 1 log vs baseline and biochemical response: ALT normalization vs baseline.

Results: Fourteen patients from six French LT centers were included. The mean age was 52 ± 9.4 years, 71.4% were men. At BLV initiation 12 patients were Child A (85.8%), 1 (7.1%) Child B and 1 (7.1%) Child C. Four (28.5%) patients received concomitant PEG IFN α 180 μ g/week. Mean MELD score was 9.14 ± 2.74 . Median platelet count 78 (26–350) $\times 10^9/L$, liver stiffness measurement (LSM) 17.4 (10–50) kPa, alanine aminotransferase (ALT) 87.5 (32–139) U/L, HBsAg 4402 (315–13899) IU/ml, HDV RNA 6 (2.23–7.4) log IU/ml. Large gastroesophageal varices were present in 9 (64%) patients. Seven (50%) patients had active HCC: 3 (43%) were BCLC-0, 3 (43%) BCLC-B and 1 (14%) BCLC-A. Eleven (78%) patients received 48 weeks (W) of BLV therapy. At W48 HDV RNA declined by a median of 2.56 (IQR 3.02) log IU/ml ($p < 0.001$) vs. baseline, becoming undetectable in 6 (54%) patients. A virological response at W48 was seen in 8 (72.7%) patients and a non-response in 1 (10%) patient. At W48 median ALT decreased to 34 (8–93) U/L ($p < 0.001$ vs baseline). Biochemical response at W48 was 72.8%. Combined response (at W48 was 54, 5%. Median MELD score was unchanged at W48. No significant changes in HBsAg concentrations were observed between W0 vs W24. No symptomatic adverse event was observed. 9 (64%) patients underwent LT after a mean waiting time of 12 (6–20) months. At LT, HDV RNA declined by a median of 1.81 (1.34) log IU/ml ($p < 0.004$) vs. baseline and was undetectable in 4 (44.4%) patients. Two patients died, one from cholangiocarcinoma and another of HCC progression. None of them were attributed to BLV.

Conclusion: BLV demonstrates safety and efficacy in patients on LT waiting list for decompensated liver disease or HCC. A 48-week course of therapy leads to significant virological and biochemical responses, providing valuable insights for the management of chronic hepatitis Delta in the LT setting.

Background and aims: Bulevirtide (BLV) is a first-in-class entry inhibitor approved in the EU for the treatment of chronic hepatitis delta (CHD). In MYR204, a Phase 2b study evaluating finite treatment with BLV with or without pegylated interferon alfa-2a (PegIFN), combination treatment resulted in higher post-treatment virologic response rates compared with either monotherapy regimen. Here we present the predictors of on-treatment and post-treatment responses with combination treatment.

Method: 174 patients with CHD were randomized (1:2:2:2) and stratified based on cirrhosis status to receive (A) PegIFN for 48 weeks (W); or (B) BLV 2 mg + PegIFN, or (C) BLV 10 mg + PegIFN for 48W followed by 48W of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96W. All patients were followed up to 48W (FU-48) post-end of treatment (EOT). In this sub-analysis, the univariate logistic regression model was used to examine whether any baseline or on-treatment clinical characteristics predicted responses at EOT and FU-24, and sustained HDV RNA undetectability at FU-48 with combination therapy (arms B and C). The assessed end points included undetectable HDV RNA (target not detected) and composite end point (undetectable HDV RNA and ALT normalization). Predictors with a p value < 0.05 was considered significant.

Results: Baseline (BL) characteristics were similar between all arms. BL predictors of undetectable HDV RNA and composite end point at EOT with combination therapy included absence of cirrhosis (odds ratio (OR) 3.6, 4.2; $p \leq 0.006$), HDV RNA $<$ median 5.54 log₁₀ IU/ml (OR 2.6, 2.5; $p = 0.03$), and LS $<$ 11.1 kPa (OR 3.8, 6.1; $p \leq 0.003$). The BL predictors of responses at FU-24 included HDV RNA $<$ median (OR 4.5, 4.0; $p \leq 0.002$), no interferon experience (only for undetectable HDV RNA, OR 2.4; $p = 0.04$), LS $<$ 11.1 kPa (OR 2.4, 3.2; $p \leq 0.04$) and lower HBsAg (OR 0.4, 0.4; $p \leq 0.02$). In patients who achieved undetectable HDV RNA at EOT (n = 51), sustained HDV RNA undetectability at FU-48 was significantly predicted by BL HDV RNA level $<$ median 5.09 log₁₀ IU/ml (OR 4.0; $p = 0.0294$), earlier onset to HDV RNA undetectability ($p = 0.0030$), and longer duration of HDV RNA undetectability ($p = 0.0029$). Importantly, achieving undetectable HDV RNA at W24 after treatment initiation predicted maintained viral suppression at FU-48 (OR 19.1; $p = 0.0005$). In patients who were undetectable at both W24 and EOT, 92% maintained treatment response at FU-48 while only 38% of patients who had positive HDV RNA at W24 and undetectable HDV RNA at EOT maintained the response at FU-48.

Conclusion: In patients with CHD treated with combination therapy with BLV + PegIFN, absence of cirrhosis, lower HDV RNA and liver stiffness at BL were identified as significant predictors of undetectable HDV RNA and composite end point at EOT. Achievement of early undetectable HDV RNA at on-treatment W24 is an important predictor of long term off-treatment viral response.

FRI-372

The effect of age and pregnancy on transition into Immune Active disease in Immune Tolerant patients—a retrospective cohort study of 245 patients

Mai Kilany¹, Edo J. Dongelmans², Jordan J. Feld³, Milan J. Sonneveld⁴, Bettina E. Hansen⁴, Harry L.A. Janssen⁵. ¹Toronto Centre for Liver Disease-University of Toronto, Toronto, Canada; ²Erasmus University Medical Center, Rotterdam, Netherlands; ³Toronto Center for Liver Disease, Toronto, Canada; ⁴Erasmus MC University Medical Center, Rotterdam, Netherlands; ⁵Erasmus MC-University Medical Center, Rotterdam, Netherlands Email: mai.kilany@uhn.ca

Background and aims: It remains unclear whether starting anti-viral therapy (AVT) in Immune Tolerant (IT) chronic hepatitis B (CHB) patients is beneficial. Patients are likely to transition into Immune Active (IA) disease over time, and is unknown whether AVT could prevent this. We longitudinally followed IT-CHB patients to identify risk factors associated with phase transition to IA and the rates of adverse outcomes (cirrhosis, hepatic decompensation and HCC).

Method: This is a retrospective single center observational study of all IT-CHB patients who were diagnosed between 1990–2020. Strict criteria for IT-disease were used: HBeAg positive, HBV DNA ≥ 6 log and if ALT ≤ 40 U/ml. IA disease was defined as ALT ≥ 80 , or >40 for two visits (in the absence of other causes of ALT elevation) or presence of $\geq F2$ on liver biopsy or non-invasive tests. KM- and Cox-method (including start of AVT as time-dependent covariate) were used for cumulative incidences and identifying predictors, in which first visit with lab was defined as baseline.

Results: In total, 245 patients were included with a median age of 29.6 [24–38] years; 68% were female and 89% were Asian. Median baseline ALT and HBV DNA were 25 [21–32] U/ml and 8.6 [8.2–9.1] log₁₀ U/ml. Those above age 40 at baseline had higher median ALT 31 [24–36] vs. 24 [20–31] U/ml ($p < 0.001$) of those <40 , but there were no differences in baseline HBV DNA level (8.7 vs. 8.6 log₁₀ U/ml, $p = 0.49$).

The median follow-up time was 142 [99–181] months. The 5- and 10 year cumulative incidences of IA transition were 38% and 61%, with a median time of 7.0 [3.2–13.8] years. 143 (58%) patients started AVT, of which IA disease was the most common indication (54%). IA transition was more common in patients with increased ALT levels at baseline (aHR 1.08, 95%CI 1.05–1.11, $p < 0.001$) and women who received short-term nucleos (t)ide analogue (NA) therapy during pregnancy (aHR 3.76; 95%CI 0.86–16.35, $p = 0.08$). For the latter group, median time between NA withdrawal and IA transition was 36 [8.2–75.1] months, excluding post-partum flares. Notably, increased age at baseline seemed not associated with a higher risk for phase transition (aHR 1.01; 95%CI 0.99–1.02, $p = 0.89$). Furthermore, changes in ALT- and HBV-DNA levels at 1- and 5-year were equal among different age groups ($<25/25-34/35-44/>45$ years, all $p > 0.05$). Regarding liver-related adverse events, four patients (1.6%) developed cirrhosis, one patient (0.4%) developed HCC approximately 6 years after transition, two patients (0.8%) achieved HBsAg-loss and no patients decompensated. All events occurred after IA phase transition.

Conclusion: A majority of IT patients transition into IA-disease within 10 years. IA transition rates were higher in patients with increased baseline ALT-levels and after short-term NA therapy during pregnancy. Interestingly, no effect of baseline age was seen.

FRI-373

Impact of pregnancy on global and HBV-specific B-cell immunity

Anna Pocurull¹, Mireia García-López¹, Cristina Collazos¹, Thais Leonel¹, Marta López², Simon Fletcher³, Elena Perpignan⁴, Georgios Koutsoudakis¹, Patricia Huelin⁵, Carlos Aracil⁵, Juan Carlos Hurtado¹, Xavier Fornis¹, Mala Maini⁶, Sofia Pérez-del-Pulgar¹, Sabela Lens¹. ¹Liver Unit, Hospital Clínic Barcelona. University of Barcelona, CIBEREHD, Barcelona, Spain; ²Gynaecology and Obstetrics, Hospital Clínic Barcelona, IDIBAPS, Barcelona, Spain; ³Gilead Sciences, Foster City, United States; ⁴Institute of Liver Studies, King's College Hospital, School of Immunology and Microbial Sciences, Faculty of Life Sciences and Medicine, King's College London, London, UK, London, United Kingdom; ⁵Arnau Vilanova University Hospital, Lleida, Spain; ⁶Division of Infection and Immunity, University College of London (UCL), London, United Kingdom
Email: pocurull@recerca.clinic.cat

Background and aims: Pregnancy represents a particular immunological state induced by the presence of the fetus. However, the role of B-cell immunity, especially regarding virus-specific B cells, has been poorly characterized, and its influence on the virological control of

chronic hepatitis B (CHB) during pregnancy remains unclear. We aimed to characterize both the global and specific humoral immunity to Hepatitis B Virus (HBV) during pregnancy and postpartum among patients with CHB. As postpartum ALT flares in HBV suggest alterations of immunity during this transition we aimed to analyze the correlates of B-cell immunity.

Method: We longitudinally collected peripheral blood mononuclear cells (PBMC) from pregnant women diagnosed with CHB (PrandHBV, $n = 22$) at multiple intervals during pregnancy (2nd and 3rd trimesters) and postpartum (weeks 6, 16, and 48), analyzing them by spectral flow cytometry. Controls included pregnant patients without HBV (Pr, $n = 9$) and non-pregnant women with CHB (HBV, $n = 9$). We studied global and memory B cells (MBC) and characterized viral antigen-specific MBC (HBsAg-MBC and HBcAg-MBC) using fluorochrome-labeled baits. Additionally, we examined follicular T cells (Tfh) and regulatory B cells (B regs). ALT flare after delivery was defined by a two-fold increase from the baseline value.

Results: In terms of global B-cell immunity, pregnancy was associated with a reduced frequency of Bregs and Tfh in both groups ($p < 0.05$). However, the percentage of atypical or dysfunctional MBC phenotype (CD21-CD27-) was higher in PrandHBV compared to Pr patients (5% vs. 3%, $p = 0.02$). The frequencies of Tfh and MBC increased after delivery, indicating a potential restoration of T cell-B cell interaction. Regarding virus-specific immunity, the frequency of HBcAg-MBC in PrandHBV patients increased post-delivery (0.4 vs. 0.9%; $p < 0.05$) whereas the frequency of HBsAg-MBC remained stable. Interestingly, PrandHBV patients who developed a postpartum ALT flare ($n = 5$), had a higher frequency of atypical HBcAg-MBC during pregnancy (5% vs 0%; $p = 0.01$).

Conclusion: While global immunity experiences changes during pregnancy, our study sheds light on the specific B-cell responses directed against HBV. The identification and characterization of virus-specific MBCs, specifically those targeting HBcAg, reveal dynamic changes post-delivery. The increased frequency of HBcAg-MBCs suggests a potential boost in the immune response following childbirth. The changes observed in HBcAg-MBC subpopulations could serve as potential indicators for predicting postpartum ALT flares. However, further studies are essential to comprehensively understand the involvement of these cells in the immunological and virological changes induced by pregnancy.

FRI-374-YI

The UK experience of liver transplantation for HBV: excellent clinical outcomes despite a significant burden of HBV/Delta disease and wide variation in hepatitis B immunoglobulin prophylaxis practices-time for a consistent approach?

Almuthana Mohamed¹, Maria Guerra Veloz¹, Silke François², Gemma Botterill³, Rachel Smith⁴, Muhammad Salman⁵, Lindsay Greenland¹, Lucy Turner⁶, Stuart McPherson⁵, Andrew Bathgate⁷, Douglas Thorburn², William Gelson⁴, Mark Aldersley⁶, Ahmed M. Elsharkawy³, Kosh Agarwal¹. ¹Institute of Liver Studies, King's College Hospital, London, United Kingdom; ²Royal Free London NHS Foundation Trust, London, United Kingdom; ³University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; ⁴Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom; ⁵The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle, United Kingdom; ⁶Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; ⁷Royal Infirmary of Edinburgh NHS Lothian, Edinburgh, United Kingdom
Email: almuthana700@gmail.com

Background and aims: Hepatitis B immunoglobulin (HBIG) along with high genetic barrier Nucleos (t)ide analogues (NUCs) are currently the standard care for prophylaxis against Hepatitis B (HBV) recurrence post liver transplantation (LT). Retrospective data from Italy suggests lifelong use of HBIG for high-risk HBV patients post-LT. However, indefinite HBIG therapy remains controversial, with heterogeneity in dosage and duration protocols in LT centres. We

POSTER PRESENTATIONS

audited the current management of HBV post-LT and outcomes within the UK for the past decade using LT centre's data.

Method: A retrospective, multicentre study was conducted by the British Association for the Study of Liver (BASL), including all patients who had LT for HBV between 2010–2023 in the 7 UK LT centres. Clinical and LT data were collected. HBV recurrence defined by reappearance of HBsAg and/or detectable HBV DNA. Multivariate regression analysis was used to identify predictors of HBV recurrence and survival.

Results: 299 patients were included (78.6% male; median age 52 years). 23.4% had HBV/Hepatitis D (HDV) coinfection. Common indications for HBV LT were decompensated cirrhosis (44.8%) and hepatocellular carcinoma (HCC) (43.5%). At the time of LT, 64.2% had undetectable HBV DNA and 69% with HBV/HDV coinfection had detectable HDV RNA. All patients with available data (96.3%) had NUCs post-LT and 81% received HBIG post-LT regardless of HBV DNA at the time of LT. However, there was heterogeneity in HBIG doses in the first week (range 0 to 10 HBIG doses) and maintenance dosing following LT (51.8% had maintenance HBIG doses, range 1 week to >10 years). During a median follow-up of 5 years, only 15 patients (5%) had HBV recurrence. Of them, 86.7% (n=13) had high-risk of recurrence pre-LT; 4 had HBV/HDV coinfection, 5 had HCC, and 4 had fulminant HBV. Out of 43 patients (14.4%) who did not receive HBIG post-LT; only 1 patient had HBV recurrence (HBsAg positive at 6 months), and 1 patient died due to non-HBV related graft failure. The median survival post-LT was 54 months (range 0–159 months), and 38 patients died with only 2 deaths related to HBV recurrence. Multivariate regression analysis showed no significant association between number of HBIG doses in the first week post-LT, maintenance HBIG and HBV recurrence (p=0.192, 0.619 respectively) or mortality (p=0.301, 0.437 respectively).

Conclusion: UK data confirms that HBV recurrence and survival are not influenced by HBIG use and that survival post-LT, including a significant component of HBV/HDV coinfecting patients, is excellent. However, most patients had prolonged maintenance HBIG doses post-LT. Almost all patients who did not receive HBIG post-LT (as per centre protocol) had no recurrence or increase in mortality. Early withdrawal or HBIG-free prophylaxis should be a strategy for most patients in a risk stratified manner, and this should be robustly reflected in clinical practice guidelines.

FRI-375

The coinfection of hepatitis C virus or human immunodeficiency virus in chronic hepatitis B in South Korea: A population-based study using the Korean Health Insurance Review and Assessment Service database

Jae Yoon Jeong¹, Won Sohn², Hyunwoo Oh^{2,3}, Hyo Young Lee⁴, Yeonjae Kim¹, Seong Woo Nam¹. ¹National Medical Center, Seoul, Korea, Rep. of South; ²Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Rep. of South; ³Uijeongbu Eulji Medical Center, Uijeongbu, Korea, Rep. of South; ⁴Inje University Sanggye Paik Hospital, Seoul, Korea, Rep. of South
Email: jyjeong76@hanmail.net

Background and aims: Concurrent infections such as hepatitis C virus (HCV) and human immunodeficiency virus (HIV) in patients with chronic hepatitis B virus (HBV) infection were associated with the development of liver cirrhosis and hepatocellular carcinoma (HCC). However, there have been few studies for on the prevalence, clinical characteristics, use of antivirals and development of liver related complications such as liver cirrhosis and HCC in HBV/HCV or HBV/HIV coinfection. This study aimed to evaluate the prevalence, comorbidities, treatment patterns and liver related complications of patients with HBV/HCV or HBV/HIV coinfection in South Korea.

Method: A retrospective, cross-sectional study was conducted using the nationwide claims data from the Health Insurance Review and Assessment Service from 2014 to 2021 in South Korea. In this study, the number of chronic hepatitis B (CHB) patients increased annually,

starting at 327, 041 individuals (221, 143 men) in 2014 and reaching 473, 811 (269, 981 men) by 2021. These patients were classified into HBV mono-infection, HBV/HCV coinfection, and HBV/HIV coinfection groups, and comparisons were made among these groups annually.

Results: The prevalence of HBV/HCV coinfection among CHB patients between 2014 and 2021 ranged from 0.76% (2, 505/327, 041 in 2014) to 1.00% (4, 053/407, 310 in 2016), while HBV/HIV coinfection prevalence ranged from 0.055% (180/327, 041 in 2014) to 0.067% (308/462, 098 in 2020). The proportion of male gender in HBV mono-infection or HBV/HCV coinfection was approximately 60%, but HBV/HIV coinfection was predominantly observed in males (over 90%). The proportion of patients aged 50 and above among CHB patients consistently increased over time (52.0% in 2014 → 65.6% in 2021), with a higher prevalence observed in the following order: HBV/HCV coinfection (70.1% in 2014 → 81.0% in 2021), HBV mono-infection (51.9% in 2014 → 65.5% in 2021), and HBV/HIV coinfection (39.4% in 2014 → 57.2% in 2021). The presence of liver-related outcomes was higher in HBV/HCV coinfection followed by HBV mono-infection and then HBV/HIV coinfection. The proportion of liver cirrhosis in HBV/HCV coinfection, HBV mono-infection and HBV/HIV coinfection was 7.4%, 5.4%, and 5.1%, respectively (p < 0.001 in 2021). Also, the proportion of HCC in HBV/HCV coinfection, HBV mono-infection and HBV/HIV coinfection was 10.6%, 6.3%, and 5.1%, respectively (p < 0.001 in 2021). Cirrhosis demonstrated a decreasing trend over time (8.5% in 2014 → 5.4% in 2021), while the development of HCC showed no significant changes (6.3% in 2014 → 6.3% in 2021).

Conclusion: Patients with HBV/HCV coinfection are older than HBV mono-infection while those with HBV/HIV coinfection was younger than HBV mono-infection in South Korea. The prevalence of liver related complications among CHB patients was highest in HBV/HCV coinfection, followed by HBV mono-infection, and then HBV/HIV coinfection.

FRI-376

The impact of alanine aminotransferase fluctuation on the hepatocellular carcinoma risk in chronic hepatitis B patients

Yongsu Park¹, Hyunjae Shin¹, Jeong-Hoon Lee¹. ¹Department of Internal Medicine and Liver Research Institute, Seoul National University College of Medicine, Seoul, Korea, Rep. of South
Email: pindra@empal.com

Background and aims: High alanine aminotransferase (ALT) levels are well-established risk factors for hepatocellular carcinoma (HCC) development in chronic hepatitis B (CHB) patients. However, the impact of ALT fluctuation around normal margin on the development of HCC remains unclear.

Method: Patients with CHB, whose ALT levels were measured at least 4 times for the first two years, were enrolled. Based on the tertiles of coefficient of variation (CV, standard deviation divided by mean) of serial ALT levels, patients were divided into low-, intermediate-, or high-fluctuation groups. The primary outcome was HCC occurrence. Baseline characteristics were balanced using the inverse probability of treatment weighting (IPTW).

Results: Among 4, 413 patients, 76 (1.7%) developed HCC during a median follow-up of 12.6 (interquartile range [IQR] = 6.9–18.7) years. The median CV values of the low-, intermediate-, and high-fluctuation groups were 0.15, 0.30, and 0.71, respectively. Because baseline ALT levels were significantly higher in the high-fluctuation group than the other groups, we focused on the comparison between the low-fluctuation (n = 1, 471) and intermediate-fluctuation groups (n = 1, 471). Before balancing the baseline characteristics, the risk of HCC was significantly higher in the intermediate-fluctuation group compared to the low-fluctuation group (hazard ratio [HR] = 2.15, 95% confidence interval [CI] = 1.18–3.90, P = 0.01). After applying IPTW, the intermediate-fluctuation group maintained a significantly higher risk of HCC than the low-fluctuation group (HR = 1.99, 95% CI = 1.07–3.68, P = 0.03). Sensitivity analyses conducted with various

definitions of ALT fluctuation also reaffirmed the consistent result of the main analysis.

Conclusion: In CHB patients without antiviral treatment, fluctuating ALT, is associated with an increased risk of HCC. Further studies are warranted to evaluate if antiviral treatment for patients with ALT fluctuation could reduce the HCC risk.

FRI-377

Decline of Serum HBV RNA level During the First Week of Nucleos(t)ide Analogues Therapy Is Associated with Liver Injury and More Efficient Clearance of Hepatitis B Virus

Liandong Wu¹, Zhenggang Yang¹, Min Zheng¹. ¹State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Infectious Diseases, National Medical Center for Infectious Diseases, Collaborative Innovation Center for Diagnosis and Treatment of Infectious Diseases, Hangzhou, China
Email: minzheng@zju.edu.cn

Background and aims: Chronic hepatitis B (CHB) is a major global health problem. Although nucleos(t)ide analogues (NAs) are effective in controlling hepatitis B virus (HBV) infection, viral eradication remains unattainable due to the persistence of covalently closed circular DNA (cccDNA). Serum HBV RNA is a non-invasive biomarker directly reflecting cccDNA transcriptional activity. It was previously demonstrated that extracellular/serum HBV RNA levels increased after NAs treatment in HBV-producing cell lines and HBV transgenic mice, while serum HBV RNA levels declined under persistent NAs therapy in CHB patients. Early change of serum HBV RNA level after NAs therapy and its influencing factors remain unclear, as well as the clinical significance.

Method: 131 treatment-naïve CHB patients were included in this prospective cohort study with 12-week follow-up. Serum HBV RNA levels at baseline and within the first week of NAs therapy were measured, and patients were divided into three cohorts according to changes in serum HBV RNA levels within the first week of NAs therapy. In cohort A (n=45), serum HBV RNA levels increased >0.5 log₁₀ copies/ml; in cohort B (n=41), serum HBV RNA levels changed <0.5 log₁₀ copies/ml; in cohort C (n=45), serum HBV RNA levels decreased >0.5 log₁₀ copies/ml.

Results: Using ordinal logistic regression, alanine aminotransferase (ALT) was found to be associated with the decreasing trend of serum HBV RNA levels within the first week of NAs therapy (odds ratio = 1.25, P < 0.001). Area under receiver operating characteristic curve (AUC) for ALT to predict patients in cohort A was 0.841 (p < 0.001); AUC to predict cohort B was 0.607 (p = 0.048); AUC to predict cohort C was 0.902 (p < 0.001). ΔHBV RNA was calculated by difference between serum HBV RNA levels from baseline to different time points under NAs therapy (posttreatment level minus baseline level). Median ΔHBV RNA of week 2 among cohorts A, B, and C were 0.55, -0.33, and -1.82 log₁₀ copies/ml, respectively (p < 0.001); median ΔHBV RNA of week 4-6 were -0.16, -0.61, and -3.18 log₁₀ copies/ml (p < 0.001); median ΔHBV RNA of week 8-12 were -0.73, -1.07, and -4.01 log₁₀ copies/ml (p < 0.001). Similarly, median ΔHBV DNA of week 1 were -1.16, -1.65, and -2.17 log₁₀ IU/ml (p = 0.013); median ΔHBV DNA of week 2 were -2.21, -2.37, and -3.02 log₁₀ IU/ml (p = 0.033); median ΔHBV DNA of week 4-6 were -3.15, -3.17, and -4.15 log₁₀ IU/ml (p = 0.015); median ΔHBV DNA of week 8-12 were -3.54, -4.19, and -5.29 log₁₀ IU/ml (p = 0.073). Median ΔHBsAg of week 4-6 were 0.02, 0.04, and -0.62 log₁₀ IU/ml (p = 0.012); median ΔHBsAg of week 8-12 were -0.03, -0.05, and -0.93 log₁₀ IU/ml (p = 0.004).

Conclusion: Serum HBV RNA levels were more likely to decline within the first week of NAs therapy in patients with more severe liver injury. Patients whose serum HBV RNA levels declined significantly within the first week of NAs therapy exhibited higher efficiency of viral clearance.

FRI-378

Effect of diabetes on the risk of fibrosis progression in patients with chronic hepatitis B

Mi Na Kim^{1,2}, Jae Seung Lee^{1,2}, Hye Won Lee^{1,2}, Beom Kyung Kim^{1,2}, Seung Up Kim^{1,2}, Jun Yong Park^{1,2}, Do Young Kim^{1,2}, Sang Hoon Ahn^{1,2}. ¹Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Rep. of South; ²Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South
Email: ahnsh@yuhs.ac

Background and aims: Diabetes is associated with a higher risk of hepatocellular carcinoma in patients with chronic hepatitis B (CHB). However, there are limited data regarding fibrosis progression in CHB patients with diabetes compared with those without diabetes. We investigated the effect of diabetes on the risk of fibrosis progression in patients with CHB.

Method: We recruited 3,450 patients with CHB who performed transient elastography from 2012 through 2020. The primary cross-sectional outcome was the prevalence of advanced fibrosis. The primary longitudinal outcome was fibrosis progression. Advanced fibrosis was defined, according to guidelines, as a liver stiffness measurement greater than 9.0 kilopascals. Fibrosis progression was defined as incident advanced fibrosis at 3-year of follow-up.

Results: The prevalence of advanced fibrosis in our cohort was 27.4% at baseline. A higher proportion of patients with diabetes had advanced fibrosis than those without diabetes (37.3% vs 24.8%; p < 0.001). In multivariate analysis, diabetes was significantly associated with advanced fibrosis (odds ratio [OR], 1.49; 95% confidence interval [CI], 1.24-1.78). The longitudinal analysis was done in 2,504 patients with fibrosis stage of F0-2 at baseline. Diabetes was significantly associated with a higher risk of fibrosis progression after multivariate-adjustment (OR, 1.98; 95% CI, 1.48-2.65). The independent association of diabetes and the risk of fibrosis progression remained in each cohort of patients without antiviral therapy (OR, 1.83; 95% CI, 1.22-2.75), and those with antiviral therapy (OR, 2.15; 95% CI, 1.42-3.27).

Conclusion: In a large, well-characterized cohort study of patients with CHB, diabetes was associated with advanced fibrosis, and a higher risk for progression to advanced fibrosis.

FRI-379

Feasibility of aMAP combined with liver stiffness assessed using transient elastography for prediction of hepatocellular carcinoma development in patients with chronic hepatitis B

Hye Yeon Chon^{1,2}, Hyung Joon Yim³, Su Jong Yu⁴, Ja Kyung Kim^{1,2}, Sang Hoon Ahn^{1,5}, Sang Gyune Kim⁶, Yeon Seok Seo⁷, Seung Up Kim^{1,5}. ¹Yonsei University College of Medicine, Seoul, Korea, Rep. of South; ²Yongin Severance Hospital, Yongin, Korea, Rep. of South; ³Korea University Ansan Hospital, Korea University College of Medicine, Ansan, Korea, Rep. of South; ⁴Seoul National University College of Medicine, Seoul, Korea, Rep. of South; ⁵Yonsei Liver Center, Severance Hospital, Seoul, Korea, Rep. of South; ⁶Soonchunhyang University College of Medicine Bucheon Hospital, Bucheon, Korea, Rep. of South; ⁷Korea University College of Medicine, Seoul, Korea, Rep. of South
Email: kskorea@yuhs.ac

Background and aims: The age-male-albumin-bilirubin-platelet (aMAP) score combined with liver stiffness (LS) assessed using transient elastography was recently suggested to be helpful for estimating fibrotic burden in patients with chronic hepatitis B (CHB). We evaluated the performance of the aMAP score combination with LS for predicting HCC development.

Method: We retrospectively reviewed 944 patients with CHB who initiated antiviral therapy in five tertiary hospitals of Korea between May 2005 and July 2021.

Results: Most patients were male (n = 527, 55.8%), and the median age was 50 years. During the follow-up period (median 47.7 months), 44 patients developed HCC. The aMAP score (66.3 vs. 60.1), aMAP-LSM_{advanced fibrosis} (aML_{af}; 97.4 vs. 72.7), and aMAP-LSM_{cirrhosis} (aML_C;

POSTER PRESENTATIONS

91.0 vs. 55.7) were significantly higher in patients who developed HCC than those who did not (all $P < 0.05$). Similarly, the PAGE-B score (16.0 vs. 12.0) and modified PAGE-B (mPAGE-B) score (12.5 vs. 10.0) were significantly higher in patients who developed HCC than those who did not (all $P < 0.05$). In multivariate analysis, an increased aMAP (hazard ratio [HR], 1.125; 95% confidence interval [CI], 1.003–1.225), aML_{af} (HR, 1.049; 95% CI, 1.005–1.095), and aML_C (HR, 1.039; 95% CI, 1.008–1.071) were independently associated with the increased risk of HCC development ($p < 0.05$). The PAGE-B score (HR, 1.163; 95% CI, 1.028–1.315) and mPAGE-B score (HR, 1.205; 95% CI, 1.006–1.445) maintained their predictive significance after adjustment ($p < 0.05$). The areas under the curve (AUROCs) at 3 years of antiviral therapy were 0.843 for aML_{af}, 0.839 for aML_C, 0.790 for aMAP, 0.764 for mPAGE-B, and 0.752 for PAGE-B, respectively. The AUROCs at 5 years of antiviral therapy were 0.802 for aML_{af}, 0.799 for aML_C, 0.752 for aMAP, 0.718 for PAGE-B, and 0.716 for mPAGE-B, respectively. The AUROCs of aML_{af} and aML_C at 3 and 5 years of antiviral therapy were significantly higher than those of the PAGE-B and mPAGE-B scores ($p < 0.05$).

Conclusion: The aMAP score combined with LS helped to predict HCC development, and its performance was superior to that of PAGE-B and mPAGE-B.

FRI-380

HBV-specific T cell specificity and functionality can be influenced by stage of chronic HBV disease, antigen levels and age

An De Creus¹, Thierry Verbinen^{1,1}, Bart Fevery¹, Simon Verheijden¹, Michael Biermer¹, Sandra De Meyer¹, Oliver Lenz¹. ¹Janssen Pharmaceutica NV, Beerse, Belgium
Email: adecreus@its.jnj.com

Background and aims: To aid the development of immunomodulatory treatments for chronic hepatitis B (CHB) patients, it is essential to better understand HBV-specific T cell immune responses at different stages of CHB infection. Therefore, we investigated breadth and functionality of HBV-specific T cells at different stages of HBV disease.

Method: Peripheral blood mononuclear cells (PBMCs) were isolated from CHB patients: not currently treated (NCT) HBeAg positive (N = 51, of which 21 were immune tolerant (IT)), NCT HBeAg-negative (N = 36), virologically suppressed (VS) HBeAg-positive (N = 25), and VS HBeAg-negative (N = 120). PBMCs were analyzed for T cell responses against peptides covering HBV core, polymerase, and surface antigens using qualified ex vivo overnight IFN γ ELISpot. ELISpot values \geq positivity threshold (PT) were considered detectable responses, values $>3 \times$ PT were considered strong responses. Association of T cell responses with viral serum markers and patient characteristics were assessed.

Results: Overall, 148/232 (64%) patients had detectable responses to at least one antigen and 8% had responses to all 3 antigens. The percentage of patients with detectable responses to surface/envelope (15%) was lower compared to core (34%) and polymerase (52%). The percentage of patients with detectable core responses was 0% in IT, low in HBeAg-positive (23% for NCT and 17% for VS) and higher in HBeAg-negative patients (44% for both NCT and VS). Overall, the percentage of patients with detectable core responses was inversely correlated with serum HBcrAg levels (51% vs 9% for <3.0 log U/ml and ≥ 7.0 log U/ml respectively). For HBeAg-negative patients with HBcrAg levels <4 log₁₀ U/ml, strong core responses were more prevalent (22%) than in HBeAg-negative patients with >4 log₁₀ U/ml (11%). Other factors that influenced frequency of detectable core responses were HBsAg levels (42% vs 22% for $\geq 10,000$ IU/ml and $<10,000$ IU/ml respectively) and age (39% vs 15% for ≥ 30 years and <30 years respectively). Age impacted percentage of patients with detectable surface responses, with trend in decreasing responses from 20% to 7% as age increased from <30 to ≥ 60 years, with no apparent impact on percentage of patients with strong surface responses. HBsAg, HBcrAg levels and HBeAg status did not correlate

with detectable surface responses. Detectable polymerase responses were not associated with disease stage, viral markers, or age.

Conclusion: This evaluation of breadth and functionality of HBV-specific T-cell responses in 232 CHB patients showed that HBV-specific T cells are detectable ex vivo in most patients across all disease stages, with differences in specificity and strength of the T cell responses by disease state, HBeAg status, HBcrAg and HBsAg levels, and age.

FRI-381

Detection of functional HBV-specific CD8+ response is associated with significant decrease of HBsAg level after treatment withdrawal in eAg (-) chronic hepatitis B

Henar Calvo Sánchez^{1,2,3}, Julia Peña Asensio⁴, Joaquín Míquel^{2,5}, Eduardo Sanz-de Villalobos^{2,4}, Alberto Delgado⁴, Miguel Torralba^{1,6,7}, Alejandro González Praetorius^{1,8}, Juan Ramón Larrubia^{1,7,9}. ¹Group of Research in Translational Cellular Immunology (GITIC), IDISCAM, Guadalajara, Spain; ²Section of Gastroenterology and Hepatology, Guadalajara University Hospital, Guadalajara, Spain; ³Department of Medicine and Medical Specialties, University of Alcalá, Alcalá de Henares, Spain; ⁴Group of Research in Translational Cellular Immunology (GITIC), IDISCAM, Guadalajara, Spain; ⁵Group of Research in Translational Cellular Immunology (GITIC), IDISCAM, Guadalajara, Spain; ⁶Service of Internal Medicine, Guadalajara University Hospital, Guadalajara, Spain; ⁷Department of Medicine and Medical Specialties, University of Alcalá, Alcalá de Henares, Spain; ⁸Section of Microbiology, Guadalajara University Hospital, Guadalajara, Spain; ⁹Section of Gastroenterology and Hepatology, Guadalajara University Hospital, Guadalajara, Spain
Email: henarcs@hotmail.com

Background and aims: Loss of hepatitis B virus surface antigen (HBsAg) is the goal upon discontinuation of nucleos(t)ide analogues (NUCs) treatment in e-antigen negative (eAg (-)) chronic hepatitis B. However, there are no clear predictive factors defining the population that will experience HBsAg loss after discontinuation of NUCs. The study aim was to evaluate the presence of a decrease in HBsAg level greater than 50% of the baseline level after discontinuation of NUC treatment according to the presence of hepatitis B virus (HBV)-specific CD8+ response against core or polymerase epitopes upon discontinuation of treatment in a 3-year follow-up.

Method: A cohort of 12 patients HLA-A2+ with eAg (-) chronic hepatitis B treated with NUCs for a mean duration of 82 months (95% CI: 64–103), 70% male, with a mean age of 46 years (95%CI 40–53) and with fibrosis $<F3$ were enrolled. At the time of suspension, the proliferative capacity of CD8+ T cells specific against core18-27 and polymerase455-63 was assessed after 10 days of antigen-specific in-vitro stimulation. HBV-specific CD8+ cells were visualized by flow cytometry after labelling with multimeric complexes and anti-CD3/anti-CD8 antibodies. Interferon-g (IFN γ) and tumor necrosis factor-alpha (TNF α) production in culture supernatants were assessed using ELISA. The HBsAg level was quantified at baseline and quarterly after discontinuation of treatment. Patients were followed for 3 years. Kaplan-Meier curves for the presence of a greater than 50% decrease in HBsAg level during follow-up were compared between the cohort with and without functional HBV-specific CD8+ cells. The number of cases that reached functional cure was recorded.

Results: 58% (7/12) of cases had CD8+ T cells specific against core and/or polymerase with proliferative capacity. The supernatants of these cultures showed significantly higher IFN γ and TNF α levels than in the non-proliferating cases (Core cultures: IFN γ $p < 0.01$; TNF α $p < 0.05$. Polymerase cultures: IFN γ $p < 0.01$; TNF α $p < 0.01$). 71% (5/7) of cases with functional HBV-specific CD8+ cells had a greater than 50% decrease in baseline HBsAg level, whereas this occurred in only 20% (1/5) of cases without functional cells, with significantly different Kaplan-Meier survival curves ($p < 0.05$). 42% (3/7) of cases with functional cells achieved functional cure, while no cases in the cohort

without functional HBV-specific CD8+ cells lost HBsAg during follow-up.

Conclusion: The presence of functional HBV-specific CD8+ T cells at the time of NUC discontinuation could select the population of patients with eAg (-) chronic hepatitis B likely to clear HBsAg.

FRI-382

The predictive value of serum HBV RNA level in chronic hepatitis B patients treated with nucleos (t)ide analogues

Yuxuan Song¹, Yandi Xie², Xiaojing Zhang³, Rongkuan Li⁴, Sujun Zheng⁵, Shuyun Zhang⁶, Ping Li⁷, Erhei Dai⁸, Xuefei Duan⁹, Juan Liu¹⁰, Bo Feng², Fengmin Lu¹¹. ¹Peking University People's Hospital, Beijing, China; ²Peking University People's Hospital, Peking University Hepatology Institute, Beijing, China; ³Hangzhou Xixi Hospital, Hangzhou, China; ⁴The Second Affiliated Hospital of Dalian Medical University, Dalian, China; ⁵Beijing You'an Hospital, Capital Medical University, Beijing, China; ⁶The Second Hospital of Harbin Medical University, Harbin, China; ⁷Tianjin Second People's Hospital, Tianjin, China; ⁸Shijiazhuang Fifth Hospital, Shijiazhuang, China; ⁹Beijing Ditan Hospital, Capital Medical University, Beijing, China; ¹⁰Research Center for Technologies in Nucleic Acid-Based Diagnostics, Hunan, China; ¹¹Peking University People's Hospital, Peking University Hepatology Institute, School of Basic Medicine, Peking University Health Science Center, Beijing, China
Email: xieyandee@163.com

Background and aims: Serum hepatitis B virus (HBV) RNA may serve as an important indicator for evaluating the efficacy of antiviral treatment and the activity of HBV in liver tissue. However, further research is needed to ascertain its accuracy and reliability. This study primarily explores the correlation between HBV RNA and other HBV markers, as well as evaluates its predictive ability on virologic response (VR), hepatitis B e antigen (HBeAg) seroconversion and hepatitis B surface antigen (HBsAg) reduction.

Method: A multicenter prospective study was conducted over a 48-week period in HBeAg-positive chronic hepatitis B (CHB) patients who were either undergoing or about to start nucleos (t)ide analog. The correlation between serum HBV RNA and dynamic changes in HBV DNA and HBsAg was described using Spearman correlation analysis. Cox regression analysis was performed to assess the predictive ability of HBV RNA on VR, HBeAg seroconversion and HBsAg reduction.

Results: A total of 427 patients from eight hospitals were enrolled who were divided into the high-viral-load group (n=214) and the low-viral-load group (n=213) based on baseline HBV RNA levels. Patients in the low-viral-load group had lower HBV DNA (p=0.009) and HBsAg (p<0.001) levels compared to those in the high-viral-load group. Serum HBV RNA levels were positively correlated with serum HBsAg levels at baseline, 24 weeks, and 48 weeks (r=0.193, p=0.008; r=0.336, p=0.004; r=0.480, p<0.001) and with HBV DNA levels at 12 weeks during follow-up (r=0.318, p=0.008). Stratified analysis revealed that these correlations were more pronounced in the high-viral-load group at baseline. During the follow-up period, 294 patients (68.9%) remained HBV RNA positive after achieving HBV DNA undetectable. A total of 162 patients (38.0%) experienced HBV RNA seroclearance with a median time of 12 weeks. Serum HBV RNA serves as an independent indicator for predicting VR (AUC=0.852, p=0.024), the seroconversion of HBeAg (AUC=0.826, p=0.003) and HBsAg reduction (AUC=0.801, p=0.002). Patients with HBV RNA below 9.12 log₁₀ copies/ml (sensitivity=0.7, specificity=0.8) at 12 weeks of treatment were more likely to be VR. Patients with HBV RNA below 4.31 log₁₀ copies/ml (sensitivity=0.8, specificity=0.8) prior to treatment were more likely to achieve HBeAg seroconversion.

Conclusion: HBeAg-positive CHB patients with higher initial HBV RNA levels have higher HBV replication capacity compared to those with lower initial HBV RNA levels. Serum HBV RNA can serve as a complementary indicator to HBsAg for better evaluation of whether patients have achieved functional cure. It can also be used as a

substitute for HBV DNA in the early stages of treatment to predict VR, particularly in patients with initially high levels of HBV RNA. Pre-treatment HBV RNA levels can predict HBeAg seroconversion during treatment.

FRI-383

Unique characteristics and risk of liver-related events among individuals with hepatitis D virus infection with and without concurrent hepatitis C virus infection: a United States administrative claims analysis

Laura Telep¹, David Wyles², Grace M. Chee¹, Anand Chokkalingam¹, Amanda Singer¹, Tatyana Kushner³. ¹Gilead Sciences, Foster City, United States; ²Denver Health Medical Center, Denver, United States; ³Icahn School of Medicine at Mount Sinai, Division of Liver Diseases, New York, United States
Email: laura.telep@gilead.com

Background and aims: Infection with hepatitis delta virus (HDV), an incomplete RNA virus that occurs only in the presence of hepatitis B virus (HBV), is associated with rapid progression to advanced liver disease including compensated and decompensated cirrhosis (CC, DC) and hepatocellular carcinoma (HCC). While some prior United States (US)-based population studies have cited high rates of HCV infection among individuals with HDV, data on the natural history of HDV/HCV infection are limited. This study characterizes the prevalence of HCV infection among individuals with HDV and examines the risk of liver-related events associated with HDV infection with and without HCV.

Method: A retrospective cohort study was conducted using the HealthVerity dataset from 2015 to 2022 that includes medical and pharmacy claims and electronic health records for more than 100 million individuals living in the US. Those included were ≥18 years at cohort entry with one year of prior continuous insurance enrollment and at least one day of available follow-up and one inpatient or two outpatient International Classification of Diseases codes for HDV and HCV. A propensity score (PS) model was constructed using baseline demographics, clinical characteristics, and treatment history, and was used to estimate hazard ratios (HRs) with 95% confidence intervals (CI) comparing risk of advanced liver disease events (CC, DC, HCC, liver transplant [LTx]) among individuals with HDV infection with and without HCV.

Results: From 2015–2022, 9,632 individuals with HDV infection met inclusion criteria, including continuous enrollment, among which 30% (n=2,885) had claims indicating concurrent HCV infection. Those with HCV were older (mean age 54.7 vs 51.5 years), more likely to be male (61.4% vs 44.3%), had more claims for severe liver disease at baseline (CC: 38.5% vs 7.1%; DC: 26.2% vs 5.4%; HCC: 7.7% vs 1.7%; and LTx: 3.7% vs 0.7%) and were more likely to have initiated treatment with hepatitis B nucleos (t)ide analogues (32.7% vs. 19.9%) or interferon (0.6% versus 0%), all with p<0.01. Approximately 25% of individuals with HCV had dispensing claims for direct acting antiviral (DAA) treatment. Baseline evidence of smoking, alcohol and substance abuse, and mental health issues was significantly higher in individuals with vs without HCV (p<0.01). After PS weighting and excluding individuals with evidence of advanced liver disease at baseline, those with HCV had a significant increased risk of developing CC (HR: 4.0, CI: 3.2–5.1). Among those with CC at baseline the risk of developing DC, HCC, or LTx was also increased with concurrent HCV: HR: 2.4, CI: 1.3–4.4.

Conclusion: Among individuals with HDV, concurrent HCV infection was not uncommon (~30%) and was associated with a notably increased risk of developing advanced liver disease. DAA treatment uptake and HDV treatment among HDV/HCV patients is needed to optimize disease outcomes.

FRI-386

Optimizing HDV diagnosis algorithm in Israel: reflex testing, prevalence of HDV seropositive individuals identified in Maccabi HealthCare services and assessment of three commercially available HDV viral load assays

Yael Gozlan¹, Rachel Shirazi², Orna Mor³, Licitia Schreiber⁴. ¹Ministry of Health, Ramat Gan, Israel; ²Ministry of Health, Tel HaShomer, Israel; ³Tel Aviv University, Tel Aviv, Israel; ⁴Maccabi MEGA lab, Maccabi Healthcare Services, Rehovot, Israel

Email: yael.gozlan@sheba.health.gov.il

Background and aims: EASL 2023 guidelines call for testing of anti HDV antibodies in all HBsAg positive cases, to identify chronic hepatitis D (HDV). Moreover, quantitation of HDV RNA viral load is highly suggested, but a significant variability between different assays does exist.

We compared the efficiency of anti-HDV reflex testing to previously performed approach in identifying individuals positive for anti HDV antibodies (HDV-Abs), determined the prevalence of HDV-RNA positives in our cohort and evaluated the results of three commercial HDV viral load assays.

Method: We reviewed HDV results in all cases tested for HBsAg in Maccabi virology laboratory since November 2021. HDV viral loads were compared between EuroBioplex, Robogene and Altona RealStar Kits.

Results: Between 1 November 2021 and 31 October 2022, 144, 512 individuals were tested for HBsAg; 1% (1276) were HBsAg positive. Only 28% (356) cases were tested for anti HDV-Abs of which 38 were anti HDV-Abs positive. Between November 2022 and 31 October 2023, after implementation of anti-HDV reflex testing, 151, 594 were tested for HBsAg; 1%, 1428, were HBsAg positive. Anti-HDV reflex testing was performed in all cases (1428, 100%) of which 77 were anti HDV-Abs positive. HDV-RNA was assessed in 97 of all these HDV-Abs positive samples and 61% (59) were found to be HDV-RNA positive. EuroBioplex, Robogene and Altona viral load assays demonstrated consistent inter-assay results, their overall agreement was high, and the average and standard deviation (\pm) Cq values were comparable (22 ± 7 , 23 ± 8 and 24 ± 9 , for the three assays, respectively). However, the average and standard deviation of viral loads quantified by each of them were different (7 ± 1.3 , 5.4 ± 1.8 and 5.9 ± 1.7 , respectively) with EuroBioplex giving the highest IU/ml values.

Conclusion: Anti-HDV reflex testing increased the number of HDV-Abs positive patients by \sim two-fold, and should be implemented in clinical practice. The majority of such patients are HDV-RNA positive presenting with high viral loads. HDV-RNA quantitation should be consistently performed with a single viral load assay, to enable accurate comparison between longitudinal viral load results.

FRI-387

Similarly low risk of hepatocellular carcinoma and cirrhotic complications in patients in the HBeAg-negative indeterminate phase compared with chronic infection

Vicki Wing-Ki Hui^{1,2,3}, Terry Cheuk-Fung Yip^{3,4,5}, Yee-Kit Tse^{3,4,6}, Jimmy Che-To Lai^{3,4,6}, Henry L.Y. Chan^{4,7}, Vincent Wai-Sun Wong^{3,4,6}, Grace Lai-Hung Wong^{3,4,6}. ¹Medical Data Analytics Centre, Hong Kong; ²Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong; ³State Key Laboratory of Digestive Disease, The Chinese University of Hong Kong, Hong Kong; ⁴Medical Data Analytics Centre, The Chinese University of Hong Kong, Hong Kong; ⁵Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong; ⁶Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong; ⁷Department of Internal Medicine, Union Hospital, Hong Kong

Email: 1155063467@link.cuhk.edu.hk

Background and aims: Patients with chronic hepatitis B virus (HBV) infection in the indeterminate phase are not covered by the current management guidelines for antiviral treatment. We aimed to

evaluate the risk of cirrhotic complications and hepatocellular carcinoma (HCC) in these patients.

Method: All non-cirrhotic patients who were negative for hepatitis B e antigen (HBeAg) at baseline were identified and classified into three HBV phases according to EASL criteria based on their first observed HBV phase: a. immune active phase (alanine aminotransferase [ALT] ≥ 40 IU/L and HBV DNA $\geq 2,000$ IU/ml), indeterminate phase (ALT ≥ 40 IU/L and HBV DNA $< 2,000$ IU/ml; or ALT < 40 IU/L and HBV DNA $\geq 2,000$ IU/ml), and inactive phase (ALT < 40 IU/L and HBV DNA $< 2,000$ IU/ml). Time-dependent crude incidence rates were used to compare the risk of cirrhotic complications and HCC across different HBV phases.

Results: We identified 55,012 HBeAg-negative patients (mean age 54 years, 51% male). At study entry, 12,325 (22.4%), 18,871 (34.3%), and 23,816 (43.3%) patients were classified into chronic hepatitis, indeterminate phase, and chronic infection respectively. Baseline HBV DNA, ALT, and FIB-4 in indeterminate group were 3.5 [1.9, 4.3] log₁₀ IU/ml, 35 [24, 58] U/L, and 1.3 [0.8, 2.1], respectively. During a median follow-up of 2.8 [1–6.4] years, there were on average 1.68 phase transitions for each patient, with around 18,000 patients having transitioned to the indeterminate phase. The time-dependent crude incidence rates of cirrhotic complications and HCC were highest in the chronic hepatitis group (18.9 and 14.0 per 1,000 person-years, $P < 0.001$ compared with the other two phases), while the rates were not significantly different between patients in the indeterminate and chronic infection phases (cirrhotic complications: 10.3 vs. 10.4, $P = 0.9$; HCC: 4.3 vs. 3.8, $P = 0.6$).

Conclusion: The risks of developing cirrhotic complications and HCC of patients in the indeterminate and inactive phases were similarly low compared to immune active phase.

FRI-388

Clinically significant liver stiffness decrease, as defined by the Baveno VII consensus, is associated with improved long-term prognosis in chronic hepatitis B patients with compensated advanced chronic liver disease

Rex Wan-Hin Hui¹, Lung Yi Loey Mak¹, Trevor Kwan-Hung Wu¹, James Fung¹, Man-Fung Yuen¹, Wai-Kay Seto¹. ¹The University of Hong Kong, Hong Kong, Hong Kong
Email: huirex@connect.hku.hk

Background and aims: The Baveno VII consensus introduced the term “clinically-significant liver stiffness (LS) decrease,” yet also highlighted that the criterion required validation. We assessed the long-term implications of clinically-significant LS decrease in chronic hepatitis B (CHB) patients with compensated advanced chronic liver disease (cACLD).

Method: We recruited CHB patients with ACLD (LS ≥ 10 kPa) and without history of clinical liver decompensation (variceal bleeding, hepatic encephalopathy or ascites) from Queen Mary Hospital, Hong Kong. Vibration controlled transient elastography (VCTE) and comprehensive blood tests were performed at baseline and year 2. Clinically-significant liver stiffness (LS) decrease was defined as LS reduction by $\geq 20\%$ with LS < 20 kPa or any LS decrease to < 10 kPa, in accordance with Baveno VII. Patients were monitored for liver-related events (hepatocellular carcinoma [HCC], decompensation, or liver-related mortality).

Results: This analysis included 317 patients (Mean baseline age 60.0 \pm 10.4, 65.3% male, 75.7% on nucleos[t]ide analogues [NUCs] at baseline for a median of 53.4 [22.6–87.3] months). The median baseline LS was 13.6 (11.5–18.8) kPa. The baseline Child-Pugh score was 5, 6 and 7 in 298 (94.0%), 16 (5.0%) and 3 (0.9%) patients respectively. In baseline treatment-naïve patients ($n = 77$), 60 patients (77.9%) were started on NUCs in subsequent follow-up, 12 patients (15.6%) refused NUCs, and 5 patients (6.5%) were not treated due to undetectable HBV DNA. VCTE was performed at an interval of 2.3 (1.9–2.7) years. The median LS at interval VCTE was 11.9 (8.8–16.9) kPa, with 155 patients (48.9%) achieving clinically-significant LS

decrease. NUC initiation in treatment-naïve patients (OR 1.945, 95% CI 1.052–3.594, $p=0.034$) and lower baseline LS (OR 0.971, 95% CI 0.944–0.999, $p=0.040$) were independent predictors of clinically-significant LS decrease. After median follow-up for 5.9 (3.3–7.8) years, 58 (18.3%) patients developed liver-related events, with 39 (12.3%), 25 (7.9%) and 16 (5.0%) patients developing HCC, decompensation, and liver-related mortality respectively. Clinically-significant LS decrease was an independent protective factor of liver-related events (14 events in patients with LS decrease vs 44 events in patients without; RR 0.201, 95% CI 0.063–0.647, $p=0.007$), whereas smoking (RR 4.443, 95% CI 1.299–15.200, $p=0.017$) was associated with increased risk. When assessing liver-related events separately, clinically significant LS decrease independently predicted lower HCC risk (RR 0.256, 95% CI 0.066–0.990, $p=0.048$), but was not associated with decompensation or liver-related mortality (both $p > 0.05$).

Conclusion: Clinically-significant LS decrease is achievable in CHB-related cACLD with NUC therapy, and is associated with improved long-term outcomes, primarily through reducing HCC risk.

FRI-389

Hepatitis delta virus infection is associated with significantly greater incidence of cirrhosis and hepatic decompensation in U.S. veterans with chronic hepatitis B

Robert Wong¹, Zeyuan Yang², Janice Jou³, Binu John⁴, Joseph K. Lim⁵, Ramsey C. Cheung¹. ¹Veterans Affairs Palo Alto Health Care System, Stanford University School of Medicine, Palo Alto, United States; ²Veterans Affairs Palo Alto Health Care System, Palo Alto, United States; ³Oregon Health and Sciences University, Portland, United States; ⁴Miami VA Medical System, University of Miami Miller School of Medicine, Miami, United States; ⁵Yale University School of Medicine, New Haven, United States

Email: rwong123@stanford.edu

Background and aims: Hepatitis delta virus (HDV) infection in patients with chronic hepatitis B (CHB) is associated with significantly greater risks of liver-related morbidity and mortality. However, data on the natural history of HDV are limited, and it remains unclear the magnitude of increased risks of cirrhosis or hepatic decompensation associated with HDV. We aim to evaluate the long-term incidence of cirrhosis or hepatic decompensation among a national cohort of U.S. Veterans with CHB with vs. without concurrent HDV infection.

Method: Using longitudinal data on all U.S. Veterans receiving care within Veteran health systems from 2010 to 2023, we identified patients with CHB with concurrent HDV infection based on laboratory testing (HDV antibody, HDV RNA, HDV antigen). Patients with cirrhosis or hepatocellular carcinoma (HCC) at time of HDV diagnosis or within 6 months were excluded. Patients with HDV were 1:2 propensity score matched to CHB patients without HDV. Incidence (per 100,000 person-years) of cirrhosis, hepatic decompensation, or HCC (censoring for death) between CHB patients with vs. without HDV were calculated using competing risks Nelson-Aalen methods for estimating cumulative hazards and compared using log-rank testing and the z-statistic as appropriate.

Results: Among 27,548 CHB patients identified, overall, 16.1% completed HDV testing and 3.25% were positive for HDV. After excluding patients with cirrhosis or HCC at baseline, 71 patients with HDV were included (95.8% male, 47.9% African American, 31.0% non-Hispanic white, 15.5% Asian, mean age 55.4 ± 12.6 years, 16.9% concurrent diabetes, 16.9% reporting high risk alcohol use), who were propensity score matched to 140 CHB patients without HDV. Compared to CHB patients without HDV, those with concurrent HDV had significantly greater incidence of cirrhosis (4.39 vs. 1.30 per 100,000 person-years, $p < 0.01$) and hepatic decompensation (2.18 vs. 0.41 per 100,000 person-years, $p = 0.01$). The risk of HCC in patients with HDV trended higher compared to CHB patients without HDV,

but did not reach statistical significance (1.28 vs. 0.41 per 100,000 person-years, $p = 0.11$).

Conclusion: Among a national cohort of Veterans with CHB in the U.S., patients with concurrent HDV infection had more than three times greater risk of cirrhosis and more than five times greater risk of hepatic decompensation compared to CHB patients without HDV. These data highlight the importance of implementing timely and appropriate HDV screening in patients with CHB to ensure early diagnosis and linkage to HDV care and management to reduce long-term risks of liver disease progression and complications.

Email: frida.abramov@gilead.com

Background and aims: Treatment guidelines permit stopping nucleos (t)ide (NA) therapy with appropriate monitoring in patients with undetectable hepatitis B virus (HBV) DNA who are non-cirrhotic and hepatitis B e antigen (HBeAg)-negative, with the aim of potentially achieving functional cure (hepatitis B s antigen [HBsAg] loss) or maintaining virological remission. This analysis characterises outcomes in the subset of patients enrolled in trials of tenofovir alafenamide (TAF) who discontinued NA therapy after up to 8 years of treatment.

Method: Patients with chronic hepatitis B (CHB), enrolled in 2 Phase 3 studies (HBeAg-negative [NCT01940341] and HBeAg-positive [NCT01940471] patients, respectively) of TAF vs tenofovir disoproxil fumarate, who discontinued study treatment for reasons other than HBsAg seroconversion after up to 8 years of treatment, and did not immediately initiate NA therapy, were required to enter a treatment-free follow-up (TFFU) phase for up to 24 weeks. During TFFU, patients were assessed at the end of their treatment (TFFU baseline [BL]) and monitored every 4 weeks for safety, including alanine aminotransferase (ALT) elevation (defined as ALT > 2 -fold TFFU BL or > 10 -fold upper limit of normal [ULN; central laboratory cutoff]) or ALT flare (defined as ALT elevation occurring at 2 consecutive visits), and for changes in HBV serology, HBV DNA, and ALT levels.

Results: Of 1298 patients enrolled in the 2 studies, 251 (19%) entered TFFU (96 [38%] were HBeAg-positive and 155 [62%] were HBeAg-negative at TFFU BL); 144 (57%) completed 24 weeks of monitoring (median [quartile (Q)1, Q3] duration, 24.0 [12.3, 24.6] weeks). Of the 107 patients who discontinued from TFFU before 24 weeks, 98 (92%) had resumed NA treatment. By missing-equals-excluded analysis in the subset who completed 24 weeks of TFFU, 31% and 63% had HBV DNA < 29 IU/ml and ALT $< \text{ULN}$, respectively, compared with 89% and 82%, respectively, at TFFU BL. Overall, 2 patients had HBsAg loss (1 with anti-HBs seroconversion); both were HBeAg-negative at TFFU baseline. A total of 60/251 (24%) patients experienced a post-

POSTER PRESENTATIONS

treatment adverse event (AE), of which 6% were Grade ≥ 3 , and 2% were serious AEs (hepatitis exacerbation [n = 5], head injury [n = 1], and plica syndrome [n = 1]). Overall, 31% had a Grade ≥ 3 laboratory abnormality, the majority being increases in aminotransferases. A total of 35/251 (14%) and 8/251 (3%) experienced ALT elevation or ALT flare, respectively. However, 69% of patients with ALT elevation could not be retested to assess flare due to lack of further follow-up. No deaths or hepatic decompensation events occurred during TFFU.

Conclusion: After up to 24 weeks of stopping NAs, viral and biochemical recurrences were frequent, and few patients achieved HBsAg loss. While severe outcomes were uncommon, close monitoring and timely resumption of NA therapy are both important to avoid adverse outcomes.

FRI-391

Relapse incidence and severe flares in chronic hepatitis B patients with lymphoma post rituximab-based chemotherapy versus HBeAg-negative hepatitis B patients without cancer after nucleos(t)ide analogue cessation

Yen-Chun Liu^{1,2}, Yu-Jia Shih², Rachel Wen-Juei Jeng¹, Chao-Wei Hsu^{1,2}, Rong-Nan Chien^{1,2}. ¹Chang Gung Memorial Hospital, Linkou branch, Taoyuan, Taiwan; ²College of Medicine, Chang Gung University, Taoyuan, Taiwan
Email: rachel.jeng@gmail.com

Background and aims: Rituximab-based chemotherapy (R-CHOP) elevates the risk of reactivation compared to solid tumor regimens, and severe flares may persist post-prophylactic nucleos(t)ide analogue (Nuc) cessation. This study investigates differences in off-Nuc clinical relapse incidence, severity, and HBsAg loss between CHB patients with lymphoma on R-CHOP and HBeAg-negative CHB patients who completed finite Nuc treatment.

Method: Non-cirrhotic HBeAg-negative CHB patients with lymphoma, HBsAg-positive, treated with R-CHOP, ceased prophylactic Nuc after >12-week post-chemotherapy extension, forming the lymphoma-CHB cohort. Their off-therapy clinical relapse, severity, and HBsAg seroclearance rates were compared with HBeAg-negative CHB patients who stopped Nuc per APASL rules (Off-Nuc cohort). Clinical relapse (CR) was defined as HBV DNA ≥ 2000 IU/ml with ALT $> 2 \times$ ULN. Severe hepatitis criteria included ALT ≥ 1000 U/L or T.Bil ≥ 3.5 mg/dL, or flares with hepatic decompensation (HD). HD was defined as T.Bil ≥ 2 mg/dL and INR ≥ 1.5 , with or without ascites or hepatic encephalopathy. Kaplan-Meier and log-rank tests compared cumulative incidence. 1:1 Propensity Score Matching (PSM) adjusted age, gender, Nuc types, pretherapy HBV DNA, and end-of-treatment HBsAg for sensitivity analysis.

Results: The lymphoma-CHB cohort (117 patients), discontinuing prophylactic Nuc post-R-CHOP, and the off-Nuc cohort (940 patients) treated with finite Nuc therapy were compared. Lymphoma patients, older (57 vs. 52 years, $P < 0.001$), less male (53% vs. 82%, $P < 0.001$), with lower HBV DNA (3.2 vs. 6.3 log₁₀IU/ml, $P < 0.001$), and ALT levels (19 vs. 167 U/L, $P < 0.001$) at treatment initiation. Off-Nuc CR incidence was comparable at 1-year (33% vs. 37%), but 2-year cumulative incidence was lower in lymphoma (34% vs. 59%, $P = 0.001$). However, off-Nuc severe flare incidence was significantly higher in lymphoma at both 1- and 2-years (24% and 24% vs. 7% and 11%). The lymphoma arm had much higher annual HBsAg loss incidence than non-cancer off-Nuc patients (4.1% vs. 1.4%, $P = 0.011$). Cox regression indicated a higher risk for severe flare in lymphoma off-Nuc patients (adjusted hazard ratio: 2.36, $P < 0.001$). Propensity score-matched cohorts (61 patients each) showed comparable CR at 1- and 2-years ($p > 0.5$), but relapse severity appeared greater in the lymphoma arm (ALT: 1315 vs. 265 U/L). The 2-year cumulative severe flare incidence remained much higher in the lymphoma group (33% vs. 10%, $P = 0.002$). Time to relapse timing also appeared shorter in the lymphoma off-Nuc patients (23 vs. 32 weeks, $P = 0.019$).

Conclusion: HBeAg-negative CHB patients with lymphoma, who stopped Nuc post-R-CHOP, showed earlier CR onset and higher off-

Nuc severe flare risk. B cell immunity changes may contribute. Stringent off-therapy monitoring is crucial for CHB patients with Rituximab-based lymphoma regimens.

Chronic HDV coinfection (CHD) is characterized by a more elevated production of Middle and Large HBsAg than HBV mono-infection, that parallels HDV replicative and cytolytic activity

Lorenzo Piermatteo¹, Stefano D'Anna¹, Antonella Olivero², Leonardo Duca³, Giulia Torre¹, Carlotta Castelli¹, Elisabetta Teti⁴, Andrea Di Lorenzo⁴, Vincenzo Malagnino⁴, Marco Iannetta⁴, Leonardo Baiocchi⁵, Simona Francioso⁵, Ilaria Lenci⁵, Francesca Ceccherini Silberstein³, Michele Milella⁶, Annalisa Saracino⁶, Alessia Ciancio², Loredana Sarmati⁴, Pietro Lampertico^{7,8}, Mario Rizzetto², Gian Paolo Caviglia², Valentina Svicher¹, Romina Salpini¹. ¹University of Rome "Tor Vergata," Department of Biology, Rome, Italy; ²University of Turin, Department of Medical Sciences, Turin, Italy; ³University of Rome "Tor Vergata," Department of Experimental Medicine, Rome, Italy; ⁴University of Rome "Tor Vergata," Department of Systems Medicine, Rome, Italy; ⁵"Tor Vergata" University Hospital, Hepatology Unit, Rome, Italy; ⁶University of Bari "Aldo Moro," Department of Biomedical Sciences and Human Oncology, Clinic of Infectious Diseases, Bari, Italy; ⁷Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; ⁸University of Milan, CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, Milan, Italy
Email: lorenzo.piermatteo@uniroma2.it

Background and aims: HBV surface proteins (HBsAg) enable HBV and HDV entry and morphogenesis. Total HBsAg comprises 3 different forms: Large- (L-HBs), Middle- (M-HBs) and Small-HBs (S-HBs) with L-HBs found in virions and not in subviral particles. Here, we investigate HBs forms levels in the setting of chronic HBV mono-infection (CHB) and HDV coinfection (CHD).

Method: 262 plasma samples from HBeAg-negative patients were included: 143 CHD and 119 CHB. Total HBsAg is measured by COBAS HBsAg II assays (Roche Diagnostics), HBs forms by ad hoc designed ELISAs (Beacle Inc) and HDV RNA by RoboGene HDV RNA Quantification Kit 2.0.

Results: CHD and CHB patients have a comparable age (median [IQR]: 54 [44–60] and 53 [39–64] years; $P = 0.8$) and rate of Nuc treatment (41.2% and 34.5%, $P = 0.3$). CHD have lower HBV DNA (median [IQR]: 1.3 [0.0–2.3] vs 1.6 [1.2–3.4] log₁₀IU/ml, $P = 0.002$) and higher ALT (median [IQR]: 79 [50–113] vs 36 [22–63] U/L, $P < 0.001$) and total HBsAg levels (median [IQR]: 5206 [827–8555] vs 1776 [354–6936] IU/ml, $P = 0.008$). Median (IQR) HDV RNA is 5.2 (3.4–6.0) log₁₀IU/ml. Notably, HBs forms composition varies between CHD and CHB with remarkably higher M-HBs and L-HBs in CHD (median [IQR]: 1127 [145–2301] vs 142 [25–707] and 2.0 [0.2–6.3] vs 0.06 [0.2–0.5] ng/ml, $P < 0.001$) despite similar S-HBs levels in the two groups (median [IQR]: 3221 [587–6497] vs 1039 [239–5438] ng/ml). Multivariable analysis confirms CHD as an independent factor associated with higher levels of M-HBs and L-HBs (OR [95%CI]: 4.7 [1.7–12–4] and 6.2 [2.2–17.9], $P < 0.002$ for both). Among CHD, the HBs forms positively correlate with HDV RNA levels (Rho = 0.48, 0.49 and 0.43 for S-, M- and L-HBs; $P < 0.001$ for all) while, in CHB, milder correlation with HBV DNA levels is observed only for L-HBs (Rho = 0.29, 0.02). Furthermore, patients with highly-replicating HDV (HDV RNA > 3 log IU/ml) show significantly higher levels of all HBs forms than lowly-replicating HDV (median [IQR] ng/ml: 4431 [1251–6950] vs 274 [25–2640] for S-HBs; 1404 [191–2484] vs 127 [4–1242] for M-HBs; 3.3 [0.2–7.8] vs 0.3 [0.04–1.1] for L-HBs, $P < 0.001$ for all). Focusing on lowly-replicating HDV patients, 43.5% have altered ALT (median [IQR]: 75 [55–93] U/L). Notably, in this set of patients, M-HBs > 200 ng/ml is the best cut-off predicting altered ALT (70% of patients with M-HBs > 200 ng/ml vs 30% with M-HBs < 200 ng/ml has ALT > 40 U/L; PPV = 70%, NPV = 76.9%; $P = 0.04$), supporting the role of M-

HBs in reflecting cytolitic activity in the setting of low HDV replication.

Conclusion: The composition of HBs forms varies in CHD and CHB patients, with CHD characterized by more elevated M-HBs and L-HBs production paralleling HDV replicative activity. This could reflect a variation in the proportion of circulating viral and subviral particles between CHD and CHB.

Overall, HBs forms can play a role in identifying patients more prone to liver disease progression, in whom treatment could be prioritized.

FRI-393

Healthcare resource utilisation and costs of hepatitis delta virus infection vs hepatitis B virus monoinfection across disease states among hospitalised adults in Italy

Pietro Lampertico^{1,2}, Valentina Perrone³, Luca Degli Esposti³, Melania Leogrando³, Chong Kim⁴, Marvin Rock⁴. ¹Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Division of Gastroenterology and Hepatology, Milan, Italy; ²CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy; ³CliCon S.r.l. Società Benefit, Health, Economics and Outcomes Research, Bologna, Italy; ⁴HEOR-Global Value and Access, Gilead Sciences, Inc., Foster City, United States
Email: chong.kim9@gilead.com

Background and aims: Hepatitis delta virus (HDV) infection occurs in individuals with hepatitis B virus (HBV) monoinfection and leads to the most severe form of viral hepatitis. In this retrospective analysis, healthcare resource utilisation (HCRU) and costs were compared between patients with HDV infection vs HBV monoinfection (HBV only) across levels of disease severity among hospitalised adults in Italy.

Method: The administrative databases of local health units in Italy (covering approximately 12 million individuals) were screened for patients aged 18 years or older who had at least 1 HDV or HBV hospitalisation discharge diagnosis (using *International Classification of Diseases, 9th Edition, Clinical Modification* codes) between 1 Jan 2009 and 30 Jun 2022. Included patients had an HDV or HBV-only diagnosis between 1 Jan 2010 and 30 Jun 2022 (identification period), no previous diagnosis, and at least 12 months of continuous enrolment before and after diagnosis. Patients' first diagnosis was used as their index date, and baseline demographics and clinical characteristics were assessed 12 months prior to the index date. Comparisons of mean per patient per year (PPPY) all-cause HCRU and costs between subgroups of liver disease severity were performed using the Mann-Whitney U test, and descriptive statistics were summarised.

Results: Of 15, 628 hospitalised patients, 14, 238 were screened for HDV infection or HBV only, and 9, 945 were included in this analysis (HDV cohort, n = 556; HBV cohort, n = 9, 389). The mean (standard deviation) age (55.8 [15.6] vs 56.8 [16.5] years, p = 0.157) and percentage of patients that were male (66.0% vs 63.6%, p = 0.248) were similar between those with HDV vs HBV only. Compared to patients with HBV only at baseline, a greater proportion of patients with HDV had compensated cirrhosis (CC; 19.6% [HDV] vs 11.5% [HBV], p < 0.001), decompensated cirrhosis (DCC; 10.4% vs 8.0%, p = 0.043), hepatocellular carcinoma (HCC; 7.6% vs 4.0%, p < 0.001), and liver transplantation (LT; 4.9% vs 0.8%, p < 0.001). Patients with HDV spent fewer months in each liver disease state than patients with HBV only. Mean (95% confidence interval) length of hospital stay (days) PPPY was significantly longer for patients with HDV vs HBV only among those with CC (92.7 [48.71–136.67] vs 48.8 [40.37–57.20], p = 0.011) and DCC (113.0 [49.22–176.75] vs 52.2 [44.57–59.77], p = 0.041). Mean total and inpatient costs PPPY were significantly higher for those with HDV vs HBV only who had CC, DCC, HCC, or LT. These costs numerically increased with disease state severity.

Conclusion: In Italy, the mean inpatient length of stay and total healthcare costs were higher for patients with HDV vs HBV only and increased with greater liver disease severity among hospitalised

adults. These findings highlight the need for early screening, diagnosis, and treatment of HDV to help reduce the clinical and economic burden of disease.

High burden of cirrhosis and increasing response rates to bulevirtide-based regimens: insights from the austrian prospective hepatitis D registry

Michael Schwarz¹, Caroline Schwarz^{1,2}, David Bauer^{1,2}, Marlene Panzer³, Michael Strasser⁴, Silvia Reiter⁵, Livia Dorn⁶, Andreas Maieron⁶, Alexander Moschen⁵, Elmar Aigner⁴, Michael Trauner¹, Albert Friedrich Stättermayer¹, Mattias Mandorfer¹, Heinz Zoller³, Michael Gschwantler², Thomas Reiberger¹, Mathias Jachs¹. ¹Division of Gastroenterology and Hepatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria; ²Department of Internal Medicine IV, Klinik Ottakring, Vienna, Austria; ³Department of Internal Medicine I, Medical University of Innsbruck, Innsbruck, Austria; ⁴First Department of Medicine, Paracelsus Medical University, Salzburg, Austria; ⁵Department of Internal Medicine 2, Johannes Kepler University Linz, Linz, Austria; ⁶Department of Internal Medicine 2, Gastroenterology and Hepatology and Rheumatology, Karl Landsteiner University of Health Sciences, University Hospital of St. Pölten, Sankt Pölten, Austria
Email: thomas.reiberger@meduniwien.ac.at

Background and aims: Chronic hepatitis D (CHD) is the most severe form of viral hepatitis, characterized by a rapid progression towards liver cirrhosis. Bulevirtide (BLV) has been approved for the treatment of CHD patients with compensated liver disease, but real-world data regarding predictors for treatment are limited. This study aimed to comprehensively characterize the Austrian cohort of CHD patients and to analyze their response to BLV treatment.

Method: CHD patients who visited one of the six participating Austrian hospitals from 2020 onwards were prospectively included. Demographic, clinical, laboratory data, liver stiffness measurement (LSM), biomarkers of systemic inflammation and single nuclear polymorphisms (SNPs) in the interleukin 28B (IL28B), Patatin-like phospholipase domain-containing protein 3 (PNPLA3), SERPINA1, and sodium-taurocholate cotransporting polypeptide (NTCP) genes were assessed in a subset of patients. Patients receiving BLV were assessed for the end points "virological response" (VR) defined as HDV-RNA decline of ≥2 log and for "combined response" (CR) defined as VR with ALT normalization at week (W)24, W48, and W96.

Results: We included 84 patients with positive HDV antibodies (median age 46 years [IQR 37–56], 57.1% male) and 59 (70.2%) had detectable HDV-RNA. LSMs available in 67 patients were: F0/1 n = 17 (25.4%), F2 n = 10 (14.9%), F3 n = 9 (13.4%), and F4 n = 31 (46.3%). Nine (10.7%) had already progressed to decompensated cirrhosis. There was no association between PNPLA3 genotype and liver disease severity (G/C or G/G: 14 [58.3%] in cirrhosis vs. 11 [68.8%] without cirrhosis, p = 0.505). BLV treatment was initiated in 50 out of 59 HDV-RNA viremic patients (F3/F4: 70.0%) and median treatment duration was 17 (8–24) months. Pegylated interferon alfa-2a (PEGIFN) was added to BLV treatment in 13 (26%) patients after a median of 10 (7–18) months. VR rates were at W24 63.0% (29/46), W48 68.4% (26/38), and W96 71.2% (16/21). CR was achieved at W24 in 19.6% (9/46), at W48 in 42.1% (16/38), and at W96 in 42.9% (9/21). We found no baseline demographic (age, sex, body mass index) nor laboratory parameters (ALT, CRP, IL-6, HDV RNA, HBV DNA, HBs antigen levels) that were predictive of VR or CR. Polymorphisms in IL28B (distribution among patients with available data: C/C: 16/33, C/T: 16/33, T/T: 1/33) as well as PNPLA3 (C/C: 13/36, C/G: 20/36, G/G: 3/36) were not associated with VR/CR to BLV at W24, W48 nor W96, respectively. No polymorphisms were found for NTCP or SERPINA1.

Conclusion: Within this prospectively characterized cohort of Austrian CHD patients we found >50% with advanced fibrosis and >10% with decompensated cirrhosis. BLV was initiated in 50 patients and increasing VR and CR rates were seen under BLV treatment for up

POSTER PRESENTATIONS

to two years. PEGIFN was added to BLV in thirteen patients. No laboratory or clinical parameters were found to predict response to BLV treatment.

FRI-395

HDV infection in Israel: epidemiology and co-morbidities

Hisham Sholy¹, Hedy Rennert², Eli Zuckerman¹. ¹Carmel Medical Center, Haifa, Israel; ²Carmel Medical Center, Haifa
Email: elizuc56@gmail.com

Background and aims: About 1–5% of people with chronic HBV infection are co-infected with HDV, however global reports from many regions are inaccurate. Epidemiological data of hepatitis D virus infection (HDV) in Israel is limited as large population-based studies have not performed so far. The aim of this study was to collect epidemiological, co-morbidities and natural history data of HDV infection in the largest population-based study performed in Israel.

Method: Data were obtained from the computerized records and database of Clalit Health Services (CHS). The database contains information regarding demographic parameters, laboratory tests and pharmacy records, hospitalization and primary care physician records and death-related data.

Results: Through 1.2002–10.2022, 1, 995, 911 out of 4, 376, 447 (45.6%) CHS ensured individuals were tested for HBsAg. Of 28, 448 positive for HBsAg (1.43%), 10, 667 (37.5%) were tested for HDV-Ab and of them, 728 were tested positive (7.01%). Only 369 HDV-Ab positive individuals were tested for HDV-RNA by PCR (50.6%) and of those, 138 (37%) were HDV-RNA positive (qualitative testing). Of 28, 448 HBsAg+ individuals, 1931 (6.8%) were younger than 20 y/o. Co-infected patients were older than HBV mono-infection (mean age 46.4 ± 14 vs. 42.5 ± 16 y/o, $p < 0.01$). The largest number of HDV-positive patients were born in Russia (28.4%) followed by Israel (23.7%), Ethiopia (19.3%), Uzbekistan (5.3%), and Morocco (4.2%). The prevalence of co-infected patients was higher in Jews compared with Arabs (3.2% vs 1.3%, $p < 0.001$). Alcohol abuse was more prevalent in the co-infection than in the mono-infection group (5.5% vs 2.5%, $p < 0.001$). As expected, the rate of liver transplantation was significantly higher in the co-infected than the mono-infected group: 39/728 (5.4%) vs only 165/27720 (0.6%) ($p < 0.001$, OR 9.4). Those with positive RNA were more likely to undergo liver transplantation than those with negative RNA (10.1% vs 0.4%, OR 25). The prevalence of cirrhosis and HCC were significantly higher among co-infected (24% vs 4.7%, $p < 0.001$, OR 6.5 for cirrhosis, 8.1% vs 1.9%, $p < 0.001$, OR 4.4 for HCC). FIB4 was calculated and reveals more significant liver fibrosis (Fib4 > 1.45) in the co-infection group (43.3% vs 23.9%). HBV-DNA was undetectable in 23.5% of positive RNA patients compared with 16.1% of RNA negative patients (NS).

Conclusion: This is the largest epidemiological study on HDV infection performed in Israel. The estimated rate of HDV infection among HBsAg-positive individuals is 7.01%. Co-infection is significantly associated with poor prognosis and higher prevalence of cirrhosis, HCC, and liver transplantation. More efforts should be directed to increase diagnosis rate and the number of treated patients.

FRI-396

Risk of hepatocellular carcinoma decreases after antiviral therapy-induced HBsAg seroclearance

Han Ah Lee¹, Hyun Woong Lee², Dong Hyun Sinn³, Sang Hoon Ahn², Beom Kyung Kim², Seung Up Kim². ¹Ewha Womans University, Seoul, Korea, Rep. of South; ²Yonsei University College of Medicine, Seoul, Korea, Rep. of South; ³Samsung Medical Center, Seoul, Korea, Rep. of South
Email: amelia86@naver.com

Background and aims: Antiviral therapy (AVT) reduces the risk of hepatitis B virus-related hepatocellular carcinoma (HCC). The difference in risk of HCC development after hepatitis B surface antigen (HBsAg) seroclearance to the AVT status was explored.

Method: Patients with chronic hepatitis B who achieved HBsAg seroclearance between 2003 and 2022 were retrospectively evaluated. The primary outcome was the development of HCC after HBsAg seroclearance.

Results: Of the study population, 1, 280 (84.2%) and 241 (15.8%) patients achieved HBsAg seroclearance without (spontaneous clearance group) and with AVT (AVT-induced clearance group), respectively. During follow-up (median 4.3 years), 37 (2.4%) patients developed HCC after HBsAg seroclearance. HCC cumulative incidence was comparable between the two groups (hazard ratio [HR] = 0.461; $P = 0.150$; log-rank test, $P = 0.197$), whereas it was significantly lower in the AVT-induced HBsAg clearance group than in the spontaneous HBsAg clearance group in the inverse probability of treatment weighting analysis (HR = 0.442; $P = 0.005$; log-rank test, $P = 0.004$). In multivariate analysis, spontaneous HBsAg clearance, albumin-bilirubin (ALBI) grade ≥ 2 , liver cirrhosis, and platelet count $< 50 \times 10^9/L$ were independently associated with the increased risk of HCC development. The newly established antiviral therapy, cirrhosis, ALBI, and platelet count (ACAP) scores had a C-index of 0.765, and the time-dependent areas under the curve of HCC prediction at 5 and 8 years were 0.774 and 0.823, respectively. The predictive model exhibited good discriminative performance in internal validation and sensitivity analysis.

Conclusion: The risk of HCC differed according to the AVT status after HBsAg seroclearance. The ACAP model may help clinicians implement timely interventions and surveillance strategies.

FRI-397

A machine learning model to predict liver-related outcomes after the functional cure of chronic hepatitis B

Moon Haeng Hur¹, Seung Up Kim², Hyun Woong Lee², Han Ah Lee³, Hyung-Chul Lee¹, Sang Hoon Ahn², Beom Kyung Kim², Hwi Young Kim³, Yeon Seok Seo⁴, Hyunjae Shin¹, Jeayeon Park¹, Yunmi Ko¹, Youngsu Park¹, Yun Bin Lee¹, Su Jong Yu¹, Yoon Jun Kim¹, Jung-Hwan Yoon¹, Jeong-Hoon Lee¹. ¹Seoul National University College of Medicine, Seoul, Korea, Rep. of South; ²Yonsei University College of Medicine, Seoul, Korea, Rep. of South; ³Ewha Womans University College of Medicine, Seoul, Korea, Rep. of South; ⁴Korea University College of Medicine, Seoul, Korea, Rep. of South
Email: pindra@empal.com

Background and aims: The risk of hepatocellular carcinoma (HCC) and hepatic decompensation persists after hepatitis B surface antigen (HBsAg) seroclearance. This study aimed to develop and validate a machine learning model to predict the risk of liver-related outcomes (LROs) following HBsAg seroclearance.

Method: A total of 2, 046 consecutive patients who achieved HBsAg seroclearance between 2000 and 2022 were enrolled from 6 centers in South Korea: the training and validation cohorts consisted of 944 and 1, 102 patients, respectively. A new model (designated as PLAN-C) was developed using variables based on the results of multivariable Cox analysis and a gradient-boosting machine algorithm. The primary outcome was the development of any LRO, including HCC, cirrhosis-related complications, and liver-related death.

Results: During a median follow-up of 55.2 (interquartile range = 30.1–92.3) months, 123 LROs were confirmed (1.1%/person-year). The PLAN-C was constructed using 6 variables: age, sex, diabetes, alcohol consumption, cirrhosis, and platelet count. Compared to previous HCC prediction models, the PLAN-C showed significantly superior predictive accuracy in both the training (c-index: 0.85 vs. 0.63–0.70, all $P < 0.001$) and the validation (0.84 vs. 0.61–0.81; all $P < 0.05$ except for CU-HCC, $P = 0.09$) cohorts. The calibration plots demonstrated a close correlation between the predicted and observed risks of LRO (Hosmer-Lemeshow test $P > 0.05$ in both cohorts). When entire patients were divided into 3 groups according to the risk predicted by PLAN-C, the low-risk group had a significantly lower 5-year incidence of LRO (0.8%), compared to the intermediate-risk (4.0%) and high-risk (22.8%) groups (both $P < 0.001$).

Conclusion: This novel machine learning model consisting of 6 variables provides reliable risk prediction of LRO after HBsAg seroclearance that can be used for personalized surveillance.

FRI-398

Targeted capture single-cell sequencing provides new insights into persistent hepatitis B virus (HBV) infection

Yanfang Huang¹, Hongyuan Xue¹, Yongping Liu², Miaoqu Zhang¹, Qiran Zhang¹, Jinhang He¹, Ning Jiang³, QuanBao Zhang¹, Zhengxin Wang¹, Chao Qiu⁴, Wenhong Zhang¹. ¹Huashan Hospital, Fudan University, Shanghai, China; ²Hangzhou Xixi Hospital, Hangzhou, China; ³School of Life Sciences, Fudan University, Shanghai, China; ⁴Institutes of Biomedical Sciences, Fudan University, Shanghai, China
Email: zhangwenhong@fudan.edu.cn

Background and aims: At the single-cell level, viral infections show significant heterogeneity. To study these infections, a technique called single-cell transcriptome sequencing which captures polyadenylated transcripts using oligo (dT) is usually used. However, this method is not very effective in capturing viral sequences as the host cellular transcriptome overwhelms, leaving only a small fraction of the viral part. To improve the detection rate of the viral sequence, we have designed five additional HBV-specific probes alongside the oligo (dT) probe to specialize in capturing HBV mRNA or DNA.

Method: Targeted capture single-cell RNA sequencing was utilized to assess the performance of the assay on a mixture of HBV-positive human HepAD38 and HBV-negative mouse 3T3. Fourteen human liver tissues were analyzed, including two healthy donors, four individuals with antiviral-naïve chronic hepatitis B, 2 HBV-associated decompensated cirrhosis, and 6 HBV-associated liver failure. In addition, humanized chimeric URG (Tet-uPA-Rag2 null- γ c null) mice (Hu-URG mice) treated with antivirals, including saline solution (used as a control, n = 2), Entecavir (n = 3) and peg-interferon (n = 2), were examined. The hepatocytes were directly observed for HBV replication and transcriptional activity using in situ hybridization.

Results: Hepatocytes that are infected with HBV have high expression of plasma proteins, lipoproteins, and coagulation-related proteins. This suggests that actively synthesizing and metabolizing hepatocytes are more supportive of HBV replication. Multiple splicing factors such as DDX5, DDX17, SRSF2, SRSF5, HNRNPH1, etc. are down-regulated in HBV-positive hepatocytes and liver failure and up-regulated in Hu-URG mice after anti-viral treatment.

Conclusion: We have developed a specialized method to detect the presence of HBV mRNA or DNA in liver cells at a single-cell resolution.

FRI-399

Hepatitis B core-related antigen is a good predictor for high risk of mother to child transmission in chronic hepatitis B

Ivana Carey¹, Mark Anderson², James Lok¹, Zillah Cargill¹, Gavin Cloherty², Geoffrey Dusheiko¹, Kosh Agarwal¹. ¹Institute of Liver Studies, King's College Hospital, London, United Kingdom; ²Department of Infectious Diseases, Abbott Diagnostics, North Chicago, United States
Email: ivana.kraslova@kcl.ac.uk

Background and aims: HBV mother to child transmission (MTCT) is preventable by HBsAg screening of all pregnant women at 1st trimester, followed by appropriate prophylaxis. WHO guidelines advise treating all HBsAg+ women with HBV DNA >200000 IU/ml from 2nd trimester together with birth dose vaccination and HBIg. While HBV DNA test is available in developed countries, access to molecular testing is sparse in resource-limited countries. Hepatitis B core-related antigen (HBcrAg) is a composite pan-genotypic serological marker, which correlates with HBV DNA levels and could be utilised in resource-limited setting. We aimed to compare HBcrAg plasma levels with other virological (HBV DNA and pre-genomic RNA) and serological markers (HBeAg status and quantitative HBsAg) in a single centre cohort of HBsAg+ pregnant patients tested at the 2nd trimester and evaluate if HBcrAg can assess the risk of HBV MTCT (HBV DNA >200000 IU/ml = high risk).

Method: Plasma samples from the 2nd trimester (median gestation 22 wks) of 1028 HBsAg+ pregnant patients with post-partum follow-up >1 year and information about their infants HBV infection status were collected between 1.1.2012–31.12.2022. We measured levels of HBV DNA by TaqMan PCR [IU/ml], quantitative HBsAg by Abbott Architect® [IU/ml], HBcrAg by CLEIA Fujirebio [log₁₀U/ml] and pgRNA by Abbott Diagnostics dual-target real-time-PCR assay [LLOQ = 0.49 log₁₀U/ml]. The results were compared according to the risk of HBV MTCT stratified by HBV DNA >200000 IU/ml = high risk vs HBV DNA <200000 IU/ml = low risk).

Results: From 1028 enrolled patients (median age 30 yrs): 668 (65%) patients were aware of HBV infection before pregnancy with 165 (16%) already on tenofovir. 144 (14%) patients were HBeAg+ and 175 (17%) had HBV DNA >200000 IU/ml. HBeAg+ patients had predominantly high HBV DNA, but there were 55 (5%) HBeAg-negative patients with HBV DNA >200000 IU/ml. Although HBsAg levels were high (>10000 IU/ml) in 360 (35%) patients, only 102 (10%) patients with high HBsAg had high HBV DNA (>200000 IU/ml). HBcrAg levels were significantly higher in patients with high viral load (7.0 vs. 3.2, p < 0.05) irrespective of HBeAg status and all patients with high HBV DNA had HBcrAg levels above 6 log₁₀U/ml. All high viral load patients had high levels of pgRNA >4.5 log₁₀U/ml. There were only 4 patients with low HBV DNA with pgRNA >4.5 log₁₀U/ml. All patients with high HBV DNA started on tenofovir at the 2nd trimester and all had pre-delivery HBV DNA levels <200000 IU/ml. No case of MTCT was reported in our cohort. ROC analysis confirmed that HBcrAg and pgRNA were able to predict more accurately high risk of HBV MTCT than HBsAg (HBcrAg AUROC = 1.0, pgRNA AUROC = 0.98 vs. HBsAg AUROC = 0.68).

Conclusion: Pregnancy plasma HBcrAg levels are more accurate than HBeAg and HBsAg levels to assess HBV MTCT risk. HBcrAg levels >6 log₁₀U/ml predict a high MTCT risk and offers a serological alternative for maternal testing.

FRI-402

The unique role of hepatitis B virus enhancer 1 in unevenly activating preS1 and preS2 promoters of integrated HBV DNA which impacts HBsAg secretion efficiency

Fengmin Lu¹, Zhiqiang Gu¹. ¹Department of Microbiology and Infectious Disease Center, School of Basic Medical Sciences, Peking University, Beijing, China, Beijing, China
Email: lu.fengmin@hsc.pku.edu.cn

Background and aims: The achievement of a “functional cure” for chronic hepatitis B (CHB) remains a formidable challenge. As another source of HBsAg, HBV DNA integration limits the achievement of a functional cure. Thus, uncovering the unique characteristics of HBsAg derived from integrated HBV DNA will shed new light on strategies for achieving a functional cure.

Method: Using clinical cohorts, animal and cell models simulating integrated HBV DNA, we explored the expression and secretion characteristics of HBsAg derived from integrated HBV DNA and the underlying mechanism.

Results: A semi-quantitative analysis of intrahepatic HBsAg protein level in 563 treatment-naïve patients revealed that, in contrast to the significantly lower serum HBsAg levels, no significant decrease of intrahepatic HBsAg protein was observed in the HBeAg-negative patients, as compared to that in HBeAg-positive patients. *In vitro* studies of integrated HBV DNA mimic and long-read RNA sequencing of liver biopsy from patients revealed that, the lower HBsAg secretion efficiency seen in HBeAg-negative patients might be attributed to a relative increased proportion of 2.4 kb HBV RNA derived from integrated HBV DNA than covalently closed circular DNA (cccDNA), which resulted in L-HBsAg over-expression and the subsequent impaired HBsAg secretion. Mechanistically, the change of 2.4 kb HBV

POSTER PRESENTATIONS

RNA proportion was caused by retargeting and uneven activation on preS1 (SP1) than preS2 (SP2) promoters by HBV enhancer 1 (Enh1) element, largely due to the loss of core promoter (CP) in integrated HBV DNA.

Conclusion: The secretion of HBsAg originated from integrated HBV DNA was impaired. Mechanistically, functional deficiency of CP leads to the promoter (s) retargeting of Enh1 and uneven activation of SP1 over SP2, resulting in an increase in proportion of L-HBsAg.

FRI-403

Evaluation of a novel hepatitis B DNA test from fingerstick capillary blood at the point-of-care as a tool to enhance clinical management

Behzad Hajarizadeh¹, Jacob George², Miriam Levy³, Ian Wong⁴, Jess Howell⁵, Gesalit Cabrera¹, Elise Tu¹, Marianne Martinello¹, Tanya Applegate¹, Gail Matthews⁶. ¹The Kirby Institute, University of New South Wales (UNSW), Sydney, Australia; ²Storr Liver Centre, Westmead Hospital, University of Sydney, The Westmead Institute for Medical Research, University of Sydney, Sydney, Australia; ³Liverpool Hospital, University of New South Wales (UNSW), South Western Clinical School, University of New South Wales (UNSW), Sydney, Australia; ⁴Blacktown Hospital, Sydney, Australia; ⁵The Burnet Institute, St Vincent's Hospital, Melbourne, Australia; ⁶The Kirby Institute, University of New South Wales (UNSW), St Vincent's Hospital, Sydney, Australia
Email: bhajarizadeh@kirby.unsw.edu.au

Background and aims: HBV DNA tests are essential to guide HBV clinical management, including antiviral treatment eligibility and effectiveness. Standard of care HBV DNA tests are expensive and need central laboratory infrastructure, limiting access while delayed time to result may interrupt continuity of care. This study evaluated the diagnostic performance of the Xpert[®] HBV Viral Load assay (Cepheid), using fingerstick capillary blood at the point-of-care compared to standard of care HBV DNA testing using venipuncture whole blood.

Method: Participants diagnosed with chronic HBV infection were enrolled from six hospital-based hepatitis clinics in Australia. Participants provided fingerstick capillary blood samples diluted 1 in 10 and tested for quantitative HBV DNA using Xpert[®] HBV Viral Load assay (adjusted lower limit of quantification: 100 IU/ml). The standard of care assay (gold standard) was Roche COBAS[®] AmpliPrep/COBAS[®] TaqMan[®] HBV DNA Test, using plasma from venipuncture whole blood samples. Sensitivity and specificity of the Xpert[®] HBV Viral Load for HBV DNA quantification were compared with the gold standard. A Bland-Altman difference plot was used to assess bias and agreement measurements.

Results: To date, 178 participants have been enrolled (recruitment ongoing, total sample size n = 300). Participants included 46% female, 19% HBeAg positive, 44% on HBV treatment, and 6% with cirrhosis, with a median age of 46 years. As measured by the gold standard test, HBV DNA was undetected in 58 participants (33%), detected <100 IU/ml in 38 (21%), and detected ≥100 IU/ml in 82 (46%; viral load range: 110 to >180 million IU/ml). Sensitivity and specificity of the Xpert[®] for HBV DNA ≥100 IU/ml (vs. <100 or undetected) was 96.3% (95%CI: 93.6, 99.1) and 89.6% (95%CI: 85.1, 94.1), respectively. Among 13 participants whose HBV viral loads fell in different categories between the Xpert[®] and gold standard assays, the difference in viral loads detected by two assays ranged from 38 to 388 IU/ml. The Bland-Altman difference plot demonstrated that HBV viral loads detected by the Xpert[®] were a mean of 0.18 log IU/ml (standard deviation 0.28) higher than those measured by the gold standard. The limits of agreement indicated that 95% of the differences between the two assays were between -0.37 and 0.74 log IU/ml.

Conclusion: This interim analysis showed minimal difference in HBV viral loads detected by the Xpert[®] compared to the gold standard assay. Among participants with inconsistent HBV viral loads between assays, the difference was not sufficient to impact clinical decision making. If validated, this fingerstick assay has the potential to

simplify clinical care for people living with HBV, particularly hard-to-reach population, and those in remote and resource limited settings.

FRI-404

To establish the threshold for transient elastography indicating advanced fibrosis in patients with chronic hepatitis B and hepatic steatosis

Fajuan Rui¹, Yee Hui Yeo², Xiaoming Xu¹, Wenjing Ni¹, Liang Xu³, Jie Li⁴. ¹Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; ²Cedars-Sinai Medical Center, California, United States; ³Tianjin Second People's Hospital, Tianjin, China; ⁴Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China
Email: lijie@sina.com

Background and aims: Transient elastography (TE) is widely recognized as an effective, non-invasive technique for diagnosing liver fibrosis by assessing liver stiffness. Although specific threshold values have been proposed separately for chronic hepatitis B (CHB) and hepatic steatosis (HS), no such recommendations exist for patients with both CHB and HS. With the rising occurrence of HS in individuals with CHB, it's increasingly important to establish a definitive TE threshold for best clinical outcomes. This study employs a substantial cohort of patients with both CHB and HS, who have undergone liver biopsy and FibroScan, to identify the precise TE threshold for detecting advanced fibrosis.

Method: The study included sequential patients with CHB and HS, who had biopsy data from 2016 to 2021 at Tianjin Second People's Hospital. The Youden index was used to find the ideal TE cutoff for patients with both CHB and HS. We calculated the Area Under the Curve (AUC) for the existing 9.7 kPa TE cutoff for patients with CHB or HS and the new optimal cutoff, comparing them using the DeLong test. Additionally, we compared AUCs for both cutoffs in subgroups with body mass indexes (BMI) below and above 25 kg/m².

Results: A total of 613 patients participated in the study, with a median age of 36. Of these, 72% (442) were male, and 12% (74) exhibited advanced fibrosis. The study determined an optimal Transient Elastography (TE) cutoff value at 8.8 kPa, which showed an AUC of 0.733. This was significantly more accurate than the AUC of 0.681 obtained using the recommended TE cutoff of 9.7 kPa (p = 0.015). In a subgroup of patients with a BMI <25 kg/m², the optimal cutoff yielded an AUC of 0.708, surpassing the AUC of 0.566 for the contemporary cutoff value (p = 0.003). The sensitivity (SE) of the optimal cutoff was higher than that of the contemporary cutoff in both the overall cohort and the BMI subgroup analysis (overall cohort: 70.27 vs. 55.41; BMI <25 kg/m²: 56.00 vs. 24.00; BMI <25 kg/m²: 77.55 vs. 71.42). However, the specificity (SP) of the optimal cutoff was lower than that of the contemporary cutoff (overall cohort: 76.25 vs. 80.71; BMI <25 kg/m²: 85.64 vs. 89.23; BMI <25 kg/m²: 70.93 vs. 75.87).

Conclusion: The optimal TE cutoff for assessing advanced fibrosis in patients with CHB and concurrent HS is 8.8 kPa, lower than the 9.7 kPa for CHB patients without HS. The optimal TE cutoff offers superior SE, making it more effective at ruling in advanced fibrosis. It's more appropriate for screening patients with advanced fibrosis, ensuring they receive the appropriate medical care. For those with both CHB and HS, a stricter (lower) TE value is needed for more accurate assessment, reflecting the unique interaction between CHB and HS and its impact on liver response and fibrosis progression.

Email: rsalpini@yahoo.it

Background and aims: A reliable quantification of serum hepatitis D virus (HDV) RNA is of paramount importance for a proper monitoring of patients under antiviral therapy. This quality control study aimed at comparing the diagnostic performances of different quantitative HDV RNA assays, used in clinical practice.

Method: Two HDV RNA sample panels were quantified at 29 Italian labs by 6 commercial assays defined as #1 (RoboGene 2.0, N = 9 labs), #2 (Eurobio on In/BeGenius ELITech platform, N = 7), #3 (Altona RealStar, N = 5), #4 (Anatolia Bosphore, N = 3), #5 (Dia.Pro.Dia., N = 2), #6 (Nuclear Laser Medicine, N = 1) and 2 in-house assays defined as #7 (N = 2). Panel A comprised 8 serial dilutions of WHO HDV genotype 1 standard from 5 to 0.5 logIU/ml, while Panel B included 20 clinical serum samples with HDV RNA from 6 to 0.5 logIU/ml. Participating labs quantified each dilution of Panel A and B 9 and 5 times, respectively (3 independent runs). Panel A was used to define assay sensitivity by estimating the 95%LOD (limit of detection). Panel B was used to evaluate assay precision by calculating the intra-run and inter-run coefficient of variation (CV). Lastly, the accuracy was assessed by calculating the differences between expected and observed values at each HDV RNA load for both Panels.

Results: By analysing Panel A, 95%LOD varied across the assays highlighting different sensitivities. In particular, #3 had the lowest median 95%LOD (10 [min-max: 3–316] IU/ml), followed by #1 (31 [3–316] IU/ml), #6 (31 IU/ml) and #2 (100 [100–316] IU/ml). The remaining 3 assays had a median 95%LOD ranging from 316 to 1000 IU/ml. Moreover, 5 assays showed a <0.5 logIU/ml difference between expected and observed HDV-RNA values for all dilutions, with #1 showing the best accuracy (Median [IQR]: 0.0 [–0.2–0.0] logIU/ml). Conversely, for #5 and #6 these differences exceeded 0.5 logIU/ml (median [IQR]: –0.7 [–0.7–0.6] and –1.3 [–1.6–1.1] logIU/ml), highlighting substantial HDV RNA underestimation. With Panel B, different reproducibility levels were observed across the assays. Indeed, #2 and #3 had a median intra-run CV <10% (median [IQR]: 8.0% [6.5%–11.2%] and 9.9% [6.8%–12.3%]) while assays #1, #4 and #7 showed a median intra-run CV from 10% to 15% and #5 and #6 of 18.9% and 26.2%. Inter-run CV depicted a similar scenario with the highest reproducibility for #2 and #3. For samples with HDV RNA <5.0 logIU/ml, five assays exhibited a <0.5 logIU/ml difference between expected and observed HDV RNA. Conversely, for HDV RNA >5.0 logIU/ml, an underestimation >1 logIU/ml was observed for most assays (N = 5).

Conclusion: This study underlines different levels of sensitivities, that could hamper the proper quantification of low level HDV RNA. There is a need to improve the accuracy in HDV RNA quantification at high viral load for most assays. These results should be carefully considered for the proper monitoring of virological response to anti-HDV drugs.

Email: joseluis.calleja@uam.es

Background and aims: Hepatitis Delta is considered the most severe form of viral hepatitis. New therapeutic options are now available and, in some countries, therapy prioritization is recommended. We aimed to evaluate the real world outcomes of HDV-infected patients with mild or moderate fibrosis in order to identify risk factors for fibrosis progression.

Method: Multicenter international retrospective study of adult patients with active HDV infection (HDV-RNA+) and absence of advanced fibrosis at diagnosis. Baseline demographical, clinical and virological variables were collected. Cirrhosis development and liver-related events (decompensation, HCC) were recorded. Patients were followed until last follow-up (FU) visit, liver transplantation (LT) or death.

Results: The cohort included 170 adult patients with mild/moderate fibrosis assessed histologically (45%) and/or non-invasively [median (IQR) age at first visit: 37 (31–45) years, males: 53%]. Most patients were Caucasians (55%) or Asians (21%), <5% were coinfecting with HIV or HCV and <15% had comorbidities (obesity, diabetes, hypertension). At baseline, only 36% of patients had ALT >2xULN. In 102 cases with LSM within year-1, median (IQR) values were 7.6 (6–9) kPa. During the study period, 33% of patients received Interferon, 36% NA and only 8% bulevirtide therapy. After a median (IQR) follow-up of 62 (21–108) months, 31 (18%) patients developed cirrhosis; of them, 5 developed liver decompensation and 2 HCC. One patient underwent LT and one patient with HCC died. Median LSM (IQR) of patients at cirrhosis diagnosis was 16 (10–17) kPa. By multivariate analysis, higher LSM at baseline (model 1) and albumin and platelet levels (model 2 excluding LSM) were the only independent predictors for cirrhosis development. The best cut-off for LSM value at baseline for cirrhosis development was 7.6 kPa (Se 84%). Neither baseline qHDV-RNA levels nor ALT influenced on cirrhosis development. In addition, 17 (10%) patients achieved HDV-RNA clearance during FU (6 after IFN therapy and 11 spontaneously) with only 1/17 patients developing cirrhosis during FU.

Conclusion: Some patients with active HDV replication and mild-moderate fibrosis may have a benign course, but up to 18% of such patients progress to cirrhosis within 5 years having increased risk for liver-related complications. LSM seems to be a reliable non-invasive predictor, as patients with LSM <7.6 kPa have a low probability of progression to cirrhosis. Dissecting the factors associated with

fibrosis progression may be useful to prioritize the need of new antiviral therapies.

FRI-407

Screening rates, prevalence, and natural history of hepatitis B/ delta virus co-infection vs. hepatitis B mono-infection: data from a large US integrated healthcare system

Varun Saxena^{1,2,3}, Lue-Yen Tucker², Xiaoran Li¹, Krisna Chai¹, Suk Seo¹, Nizar Mukhtar¹, Grace M. Chee⁴, Kyung Min Kwon⁴, Sreepriya Balasubramanian¹, Brock Macdonald¹, Julie Schmittiel².
¹Kaiser Permanente Northern California, Oakland, United States; ²Kaiser Permanente Northern California Division of Research, Oakland, United States; ³University of California San Francisco, San Francisco, United States; ⁴Gilead Sciences Inc., Foster City, United States
Email: varun.saxena@kp.org

Background and aims: Hepatitis delta virus (HDV) among patients with chronic hepatitis B virus (HBV) is the most severe form of viral hepatitis. Despite this, HBV/HDV co-infection prevalence in the United States (US) remains uncertain. In this study, we aim to demonstrate screening rates of HDV, estimates of HBV/HDV prevalence, and natural history data of HBV/HDV vs. HBV alone from a large US integrated healthcare system.

Method: In this retrospective cohort study from Kaiser Permanente Northern California, an integrated healthcare system with over 4.6 million patients, all adult HBV infected patients identified from January 2009 to December 2018 were included. Proportions of anti-HDV testing, positive anti-HDV, HDV RNA testing, and detectable HDV RNA were studied. Three groups were identified: HBV mono-infected (included those without anti-HDV testing), HBV with anti-HDV positive (included those without HDV RNA testing) and HBV/HDV co-infected (those with detectable HDV RNA). Groups were followed until outcome of interest, insurance loss or study termination at end of 2022. Outcomes of interest included fibrosis progression (at least 1 fibrosis stage increase between serial transient elastography measurements), cirrhosis, decompensated cirrhosis, hepatocellular carcinoma (HCC), liver transplantation and all-cause mortality.

Results: We identified 17,794 HBV infected patients, of which 10,461 (59%) underwent anti-HDV testing. 83 of 10,461 patients (0.8%) were anti-HDV positive; 73 of 83 (88%) had HDV RNA tested and 11 of 73 (15%) were HDV RNA detectable. Among the HBV mono-infected (n = 17,700) vs. HBV with anti-HDV positive (n = 83) vs. HBV/HDV (n = 11) patients, baseline characteristics showed highest proportion of female in HBV mono-infected (47%), median age youngest in HBV/HDV (44 years) and highest BMI in HBV/HDV (27 kg/m²) (all p < 0.05). For comorbidities, diabetes and hypertension were highest in HBV with anti-HDV positive (23% and 13% respectively) with active tobacco users highest in HBV/HDV (10%) (all p < 0.05). The HBV/HDV had the highest proportion of patients with baseline cirrhosis at 45% (p < 0.05). HBV/HDV (vs. HBV with anti-HDV positive vs. HBV mono-infected) showed the most fibrosis progression (100% vs. 15% vs. 11%), cirrhosis development (75% vs. 18% vs. 7%), decompensation development (30% vs. 7% vs. 0.6%), liver transplantation (18% vs. 6% vs. 0.4%), and mortality (18% vs. 11% vs. 6%) (all p < 0.05). HCC development was most common in HBV with anti-HDV positive at 11% vs. 9% in HBV/HDV vs. 2% in HBV mono-infected (p < 0.01).

Conclusion: From this large US HBV cohort, HDV screening rate was 59%, revealing <1% anti-HDV positive rate and 0.1% HBV/HDV prevalence. The findings support the aggressive nature of HDV infection and that of HDV exposure as well. Controlled cox-regression analysis will be presented to confirm HDV as the cause for the more severe natural history.

FRI-408

Statins in untreated chronic HBV link with improved survival, liver outcome and inflammation: a large multicenter retrospective real-world cohort study

Mohammed Suki¹, Tamer Safadi², Yael Milgrom¹, Mohamad Masarowah¹, Wadiaa Hazo¹, Yariv Tiram¹, Johnny Amer¹, Abed Khakayla¹, Ashraf Imam¹, Esther Forkosh¹, Joseph Sackran¹, Ofer Perzon¹, Ahmad Salhab¹, Sylvia Drazilova², Peter Jarčuška², Rifaat Safadi¹. ¹Liver institute, Hadassah Hebrew University Hospital, Jerusalem, Israel; ²2nd Department of Internal Medicine, University Hospital and Faculty of Medicine, Pavol Jozef Šafárik University, Košice, Slovakia
Email: johnnyamer@hotmail.com

Background and aims: Statins link to antiviral and immunomodulatory properties that could benefit chronic hepatitis B virus (HBV) infection. However, clinical data remains restricted to small-scale unmatched trials. This large real-world retrospective cohort study assessed long term outcomes of statins in chronic HBV patients without anti-viral.

Method: TriNetX is a global research platform de-identified database that spanning 135 million patients across 112 healthcare organizations worldwide. We analyzed electronic medical records of 11569 HBV mono-infected adults (18–90 years) during 2003–2023 from the TriNetX network. Patients defined as detectable HBV DNA >10 IU/ml, never treated with HBV anti-viral (at index event and along 15 follow-up years), either started statins only at index event or never treated with statins. Exclusion criteria were ALT and ALP levels >4 UNL, liver transplants, HCC, and past anticoagulation therapy. Outcomes assessed over 1, 5, 10 and 15 years; including mortality and survival, laboratory data (biochemical, hematologic, AFP), manifestations and complications of cirrhosis, viral load trajectories, as well as metabolic and cardiovascular (CV) outcomes. Advanced liver disease and complications of cirrhosis were defined according to ICD9 terms, blood tests (albumin, bilirubin, INR, Platelets) and specific treatments (NSBB, ammonia lowering agents and spironolactone).

Results: Following an extensive matching of 44 clinical and laboratory parameters, propensity score matching created 2 balanced groups for analysis, statin-exposed (n=935) and unexposed (n=935). Despite extensive matching, LDL remained significantly higher in the statin group, with a non-significant trend of higher TG and HBA1c at baseline. Statin group demonstrated a significant improvement in mortality and survival (p < 0.005), as well as manifestations of advanced liver disease (p < 0.05), but not HCC and neither liver transplant. Although BMI remained similar in both groups, the statin group exhibited a significant LDL and AST improvements and HBA1c worsening, while CV events equalized. Interestingly, viral load kept similar in both groups in all tested time points.

Conclusion: This long-term real-world study in HBV patients suggests effectiveness of statins on survival and liver outcomes despite the higher metabolic risks at baseline (lipid profile) and along follow-up (HBA1c worsening). Statins improved LDL and equalized CV events despite higher metabolic risks, suggesting survival improvement because of the liver alleviation. Ongoing similar viral load in both groups and AST decline in statin group suggesting an anti-inflammatory mechanism but not a direct viral effect.

FRI-409

Enhancing hepatitis delta diagnosis in southern Spain: efficacy and cost-effectiveness of double reflex testing

Email: anafuenteslop@gmail.com

Background and aims: Hepatitis delta is a significant global health concern, affecting an estimated 15 to 20 million people worldwide. With the recent introduction of Bulevirtide, the first antiviral specifically for hepatitis delta, and forthcoming new antivirals targeting hepatitis B virus, there are now more therapeutic options. These developments could enhance elimination strategies. Our study focuses on assessing the prevalence of undiagnosed hepatitis delta in Southern Spain (Andalusia) and evaluating the feasibility and cost-effectiveness of reflex testing for hepatitis delta.

Method: We conducted an ambispective (both retrospective and prospective) multicentre study across 17 hospitals in Andalusia. During the retrospective phase (January 2018 to June 2022), we analyzed the hepatitis delta diagnostic process, focusing on patients positive for HBsAg. We identified those tested for anti-delta antibodies and those who underwent HDV RNA testing, extracting data from the Laboratory Information Systems (LIS) of participating centers. From October 2022 to March 2023, all centers began the prospective phase, implementing reflex testing for hepatitis delta (testing for anti-HDV in all HBsAg-positive patients who hadn't been previously tested). We evaluated the cost-effectiveness of implementing reflex testing in the prospective phase population versus non-implementation, considering only direct healthcare costs (screening and diagnosis), excluding treatment costs.

Results: In the retrospective phase, we analyzed 18, 583 HBsAg-positive patients. Of these, 3436 (18%) underwent anti-HDV testing, with 205 (6%) testing positive. HDV RNA testing was conducted on 158 patients, identifying 69 (1.9%) as HDV-RNA positive. In the prospective phase, of 3, 370 HBsAg-positive patients, 986 had prior anti-HDV testing. Of the remaining 2, 384, 2, 293 (96%) were tested for anti-HDV, with 109 (4.7%) testing positive. HDV RNA was tested in 97 of these 109 patients (89%), resulting in 30 patients (1.3% of all HBsAg-positive, 31.6% of HDV-RNA tested) being identified as HDV-RNA positive. In the cost-effectiveness analysis, we observed a cost

POSTER PRESENTATIONS

saving of €132 per HBsAg positive screened of anti-HDV patient and €6, 246 per patient diagnosed with a positive HDV viral load.

Conclusion: Our retrospective analysis reveals an under-diagnosis of HDV in Southern Spain, with only a fifth of HBsAg-positive patients screened for anti-HDV from 2018 to early 2022. Implementing double reflex HDV testing has proven feasible and significantly increases the detection of chronic HDV infection. This approach is crucial in identifying “missing” hepatitis delta patients. Furthermore, our findings suggest that reflex testing for HDV in HBsAg-positive patients is an efficient strategy.

FRI-410

Mitochondrial dysfunction and metabolic plasticity in the hepatitis B virus specific immune response: new insights and implications for hepatitis B virus cure

Saima Ajaz¹, Riham Soliman¹, James Lok¹, Kosh Agarwal¹. ¹Institute of liver studies, King's College Hospital NHS Foundation Trust, London, United Kingdom

Email: saima.ajaz@nhs.net

Background and aims: Hepatitis B virus (HBV) is a leading cause of cirrhosis and hepatocellular carcinoma. Chronic infection is characterized by an exhausted adaptive immune response in which there is reduced proliferative capacity and altered ATP biogenesis. Our aim was to explore the metabolic profile of these immune cells in more detail, including amongst those treated with nucleos(t)ide analogues (NUC).

Method: For this cross-sectional study, adult subjects were divided into three groups: Group 1 (healthy controls, HC, n = 10), Group 2 (chronic HBV infection, NUC suppressed, n = 16) and Group 3 (chronic HBV infection, not currently treated, n = 6). Peripheral blood mononuclear cells were extracted from whole blood using density gradient centrifugation and 300, 000 cells/well were selected for downstream analysis. Oxygen consumption rate (OCR; basal, ATP-linked, and maximal), extracellular acidification rate (ECAR) and reserve capacity were assessed using the Seahorse XFp analyzer (Agilent Technologies). Dependency of mitochondrial respiration for different substrates was explored using the XFp Cell Mito Stress Test Kit, including selective inhibition of glucose, glutamine, and long chain fatty acid pathways.

Results: Subjects were matched for key demographic characteristics, including age (45.5 ± 9.9), sex (male: female ratio of 12:10) and BMI (29 ± 6.5 kg/m²). HBV-infected individuals demonstrated greater reliance on glucose for ATP generation, irrespective of their treatment status; however, they were significantly less efficient at oxidative phosphorylation when compared to healthy controls (ATP-linked respiration rate 14.6 ± 5.7 vs 87.8 ± 47 pmol/min, p = 0.006). Inhibition of glucose pathway led to an increase in maximal respiration rate amongst HBV patients who were not currently treated (315 pmol/min versus 221 pmol/min); this indicates metabolic flexibility and the potential to activate alternative pathways. Similar compensatory mechanisms were not observed in the NUC-suppressed population, as shown by a reduction in maximal respiration after glucose interference (202 pmol/min versus 312 pmol/min). The same cohort also demonstrated a lower basal respiration rate (93.5 ± 22 pmol/min, p < 0.05), compared with HC (193.5 ± 38 pmol/min) and individuals not on NUCs (192.4 ± 45 pmol/min).

Conclusion: In chronic HBV infection, the adaptive immune response preferentially upregulates glycolysis at the expense of oxidative phosphorylation. This phenomenon, which is reminiscent of the Warburg effect, may contribute to their exhausted phenotype and ultimately HBV persistence. We demonstrate that these immune cells are adaptable and can promote alternative metabolic pathways under the right conditions; manipulation of their metabolic profile, perhaps in combination with checkpoint modulation, represents a viable therapeutic strategy.

FRI-411-YI

Proportions of indeterminate phase of patients with chronic hepatitis B virus infection according to different international guidelines

Shaoqiu Zhang¹, Chao Jiang², Jian Wang^{1,3}, Zhiyi Zhang⁴, Fei Cao⁴, Li Zhu⁵, Ye Xiong⁴, Tao Fan⁴, Xiaomin Yan¹, Yuxin Chen⁶, Chuanwu Zhu⁵, Xingxiang Liu⁷, Jie Li^{1,3,4}, Chao Wu^{1,3,4}, Rui Huang^{1,2,3,4}. ¹Department of Infectious Diseases, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; ²Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Jiangsu University, Nanjing, China; ³Institute of Viruses and Infectious Diseases, Nanjing University, Nanjing, China; ⁴Department of Infectious Diseases, Nanjing Drum Tower Hospital Clinical College of Nanjing University of Chinese Medicine, Nanjing, China; ⁵Department of Infectious Diseases, The Affiliated Infectious Diseases Hospital of Soochow University, Suzhou, China; ⁶Department of Laboratory Medicine, Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, Nanjing, China; ⁷Department of Hepatology, Huai'an No. 4 People's Hospital, Huai'an, China

Email: doctor_hr@126.com

Background and aims: Definitions of natural phases of chronic hepatitis B virus (HBV) infection vary among international hepatitis B guidelines. A considerable number of patients with chronic HBV infection do not fit into usual phases and were classified into “indeterminate phase.” We compared the proportions of indeterminate phase among different international guidelines.

Method: A total of 9, 694 treatment-naïve patients with chronic HBV infection were included from three medical centers. Patients were classified as different natural phases according to guidelines by the 2018 American Association for the Study of Liver Diseases (AASLD), the 2017 European Association for the Study of the Liver (EASL) and the 2015 World Health Organization (WHO). Patients fall outside the defined phases by international guidelines were defined as indeterminate phase. Each natural phase has its corresponding indeterminate phase and thus the indeterminate phase was further divided into four subcategories. Significant liver fibrosis was estimated by non-invasive tests.

Results: The proportion of indeterminate phase of patients with chronic HBV infection was highest according to the definitions by WHO guidelines (36.93%), followed by AASLD guidelines (27.69%) and EASL guidelines (25.96%). The proportion of patients with indeterminate phase increased significantly with age. With regards to different indeterminate phase subtypes, the proportion of indeterminate phase corresponding to HBeAg-negative CHB (HBeAg-negative chronic hepatitis B) was highest according to WHO guidelines (76.54%) followed by EASL (54.43%) and AASLD (38.22%) guidelines (p < 0.001). The proportion of significant liver fibrosis in patients with indeterminate phase were comparable among different international guidelines (EASL: 15.92%; AASLD: 15.21%; WHO: 13.79%, p = 0.117). However, patients with indeterminate phase corresponding to HBeAg-negative CHB had a higher rate of significant fibrosis in EASL guidelines (19.38%) compared to AASLD guidelines (16.91%) and WHO guidelines (14.48%) (p = 0.006).

Conclusion: The proportion of indeterminate phase in chronic HBV-infected patients varied among international hepatitis B guidelines and was lowest according to the definition by EASL guidelines. There is no significant difference in the rates of significant liver fibrosis in patients with indeterminate phase among three guidelines. However, patients in the indeterminate phase corresponding to HBeAg-negative CHB had higher proportion of significant liver fibrosis according to EASL guidelines.

FRI-412

Quantification of plasma hdv rna in untreated and bulevirtide-treated patients with chd: a comparison between robogene 2.0, eurobioplex and altostar

Maria Paola Anolli¹, Sara Uceda Renteria², Elisabetta Degasperi¹, Floriana Facchetti¹, Dana Sambarino¹, Marta Borghi¹, Riccardo Perbellini¹, Roberta Soffredini¹, Sara Monico¹, Ferruccio Ceriotti¹, Pietro Lampertico^{1,3}. ¹Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ²Virology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ³CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy
Email: sara.ucedarenteria@policlinico.mi.it

Background and aims: Accurate HDV-RNA quantification is crucial for diagnosis and management of chronic hepatitis Delta, yet a significant variability between assays do exist. We compared three methods to quantify HDV-RNA levels in untreated and Bulevirtide (BLV)-treated CHD patients.

Method: Frozen plasma from untreated and BLV-treated CHD patients were tested in a single-center retrospective study: Robogene HDV-RNA Quantification Kit 2.0 (Roboscreen GmbH; LOD 6 IU/ml on 7500 Fast Real-Time PCR System [Applied Biosystem]), EurobioPlex HDV PCR quantitative (Eurobio Scientific, LOD 100 IU/ml) on CFX96™ real-time PCR detection system [Bio-Rad] and AltoStar HDV RT-PCR Kit 1.5 (Altona Diagnostics; RUO test, estimated LOD <10 IU/ml).

Results: Overall, 429 plasma samples from 130 CHD (69 untreated and 61 BLV-treated) patients were studied. Median HDV-RNA were higher with Robogene than EurobioPlex [3.78 (0.70–7.99) vs. 4.69 (2.00–8.19) Log IU/ml, $p < 0.0001$]. Compared to Robogene 2.0, EurobioPlex reported similar HDV-RNA ($\Delta \pm 0.5$ Log) in 66 (28%) patients but higher >0.5 Log in 160 (69%). Viremia was lower with Robogene than AltoStar [3.32 (0.70–7.37) vs. 3.91 (0.19–7.54) Log IU/ml, $p < 0.0001$]. AltoStar reported HDV-RNA levels >0.5 Log in 127 (52%). Virological response at week 24 (Robogene vs. Eurobio and AltoStar) and 48 (Robogene vs. AltoStar) did not differ. HDV-RNA undetectability rates at week 24 were 11% vs. 33% with Robogene vs. EurobioPlex, and 11% vs. 3% Robogene vs. AltoStar. At week 48, 47 samples collected at on treatment week 48 were analyzed with the three tests: HDV-RNA levels were 3.04 (0.70–6.20) IU/ml vs. 3.62 (2.00–7.12) vs. 3.37 (0.28–6.45) IU/ml with Robogene vs. EurobioPlex vs. AltoStar, respectively ($p = 0.36$). At week 72 HDV-RNA was undetectable in 42%, 83% and 25% of patients, respectively.

Conclusion: HDV-RNA levels quantified by EurobioPlex and Altostar were 1 and 0.5 logs higher than Robogene 2.0, respectively. HDV-RNA undetectability rates during BLV differed according to the method.

FRI-413

Prevalence, fate and implication of gray zone on the trajectory of hepatitis B surface antigen in treatment-naïve young adults with chronic hepatitis B infection

Lung Yi Loey Mak¹, Apostolos Koffas², Grace Dolman², Yu Lei³, Anna Riddell², Upkar Gill², Patrick Kennedy². ¹The University of Hong Kong, Queen Mary University of London, Hong Kong, China; ²Queen Mary University of London, London, United Kingdom; ³Chongqing Medical University, Queen Mary University of London, London, United Kingdom
Email: loeymak@gmail.com

Background and aims: Chronic hepatitis B (CHB) patients designated in the grey zone (GZ) are currently excluded from treatment. We aimed to characterize the prevalence of GZ patients and the dynamic profiles of quantitative hepatitis B surface antigen (qHBsAg) in young adults under long-term follow-up.

Method: Treatment-naïve CHB patients aged ≤ 30 were prospectively recruited with serum qHBsAg (in IU/ml), hepatitis B virus (HBV) DNA (in IU/ml) and alanine aminotransferase (ALT, in U/L) longitudinally

monitored. Disease phases were classified according to EASL guidelines, while GZ was defined when the hepatitis B e antigen (HBeAg)-ALT-DNA profile does not fall into any phases, i.e., GZ-A: HBeAg+, ALT ≤ 40 , HBV DNA $< 1 \times 10^6$; GZ-B: HBeAg+, ALT > 40 , HBV DNA $< 2 \times 10^4$; GZ-C: HBeAg-, ALT ≤ 40 , HBV DNA > 2000 ; GZ-D: HBeAg-, ALT > 40 , HBV DNA ≤ 2000 .

Results: A total of 250 patients were recruited (median age 26 years [interquartile range 22–29], 46.4% male, predominant genotype D, 36% White/43.2% Black/17.6% Asian/3.2% unknown). At baseline, 24% were HBeAg-positive, with 28.4% falling into the GZ (A: 2.4%, B: 0.8%, C: 22.8%, D: 2.4%). Over a median follow-up (FU) of 56.5 months, median qHBsAg decreased from 8255 to 7138 ($p < 0.001$). Interestingly, at long-term FU, 29.2% patients experienced an increase in qHBsAg from baseline, more commonly observed in patients with higher qHBsAg levels at 12 months (OR 2.257, 95% CI 1.120–4.500) and patients showing increase in qHBsAg at 12 months compared to baseline (OR 7.556, 95% CI 2.412–23.667). HBsAg seroclearance was observed in 3.8%. After censoring 13 patients started on nucleoside analogues during FU, the proportion of GZ patients reduced to 19.9% (A: 2.2%, B: 0%, C: 12.9%, D: 4.3%). Proportion of patients achieving qHBsAg < 100 and qHBsAg < 1000 increased from 6.4% to 10.4%, and 15.6% to 21.7%, respectively, at long-term FU. Male gender (OR 2.702, 95% CI 1.031–7.080), baseline qHBsAg (OR 0.015, 95% CI 0.002–0.114), serial change in qHBsAg level (OR 0.036, 95% CI 0.005–0.246) and GZ at 12 months (OR 0.103, 95% CI 0.013–0.833) were associated with achieving qHBsAg < 1000 at long-term FU.

Conclusion: More than 25% of young treatment-naïve CHB patients were designated as GZ and the prevalence declined with age, together with a general decline in qHBsAg. A subset of patients demonstrated serial increase in serum qHBsAg levels over long-term FU. GZ and dynamic increase in qHBsAg were associated with higher qHBsAg levels and should be considered for treatment.

FRI-414

Hepatitis B treatment in Africa: experiences from a scale-up program in Ethiopia

Lasse Rossvoll¹, Hailemichael Desalegn², Fikadu Girma Gudissa³, Dawit Birhanu⁴, Ahmed Hussien⁵, Waqtola Cheneke⁶, Asiya Jeylan³, Esayas Gudina⁶, Nega Berhe⁷, Asgeir Johannessen¹. ¹Vestfold Hospital Trust, Tønsberg, Norway; ²St.Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia; ³Adama Comprehensive Specialized Hospital Medical College, Adama, Ethiopia; ⁴Dubti General Hospital, Dubti, Ethiopia; ⁵Jigjiga University Sheikh Hassen Yabare Comprehensive Specialized Hospital, Jigjiga, Ethiopia; ⁶Jimma University, Jimma, Ethiopia; ⁷Addis Ababa University, Addis Ababa, Ethiopia
Email: lasse.rossvoll@gmail.com

Background and aims: In sub-Saharan Africa treatment for chronic hepatitis B (CHB) is rarely available, and data on the management of CHB from this region is scarce. In 2021/22 we set up a scale-up CHB treatment program at four regional hospitals in Ethiopia. Here we present early experiences from this public-sector scale-up program.

Method: A total of 5, 863 HIV-negative adults with CHB were enrolled between December 2021 and December 2023. The patients were assessed with laboratory tests, including viral markers and liver enzymes. The treatment eligibility criteria were: i) clinically diagnosed cirrhosis, ii) aspartate aminotransferase to platelet ratio index (APRI) ≥ 0.7 , iii) alanine aminotransferase (ALT) > 40 U/L and HBV DNA $> 2,000$ IU/ml, and iv) hepatocellular carcinoma in first-degree relative and HBV DNA $> 2,000$ IU/ml. Tenofovir disoproxil fumarate was the preferred antiviral drug and was provided free of charge.

Results: The median age was 30 years (interquartile range 25–38) and 2, 861 (48.8%) patients were women. Coinfection with HCV was uncommon ($n = 92$; 1.6%). Most patients had normal (≤ 40 U/L) ALT ($n = 4, 277$; 72.9%) and low (≤ 0.5) APRI ($n = 4, 399$; 75.0%). At inclusion, 3, 697 (63, 1%), 986 (16, 8%) and 1, 052 (17, 9%) had HBV DNA $< 2,000$ IU/ml, 2000–19, 999 IU/ml and $\geq 20,000$ IU/ml, respectively.

POSTER PRESENTATIONS

Overall, 2, 954 (50.4%) patients were classified as inactive carriers, defined as HBV DNA <2, 000 IU/ml and ALT ≤40 U/L. 1, 002 (17.1%) patients had APRI ≥0.7, suggestive of cirrhosis. Male sex (adjusted odds ratio (AOR) 3.45; 95% CI 2.93–4.07) and HBV DNA >2, 000 (AOR 3.13; 95% CI 2.70–3.62) were independently associated with cirrhosis. In total, 1, 571 (26.8%) patients were eligible for treatment at baseline evaluation.

Conclusion: Roughly 25% of the patients were eligible for treatment at enrollment, highlighting the importance of improved access to CHB treatment in sub-Saharan Africa. Another 25% were indeterminate and would need longitudinal follow-up to determine treatment eligibility. The remaining 50% were classified as inactive carriers and could probably have less intensive follow-up.

FRI-415

Hepatitis B virus genotype and some baseline characteristics, but not race, affect HBsAg kinetics during nucleos (t)ide analogue therapy

Rachel Wen-Juei Jeng^{1,2}, Margarita Papatheodoridi³, Yen-Chun Liu^{1,2}, Emilia Hadziyannis⁴, Spiros Manolakopoulos⁴, Rong-Nan Chien^{1,2}, George Papatheodoridis³. ¹Chang Gung Memorial Hospital, Linkou Medical Center, Department of Gastroenterology and Hepatology, Taoyuan, Taiwan; ²Chang Gung University, College of Medicine, Taoyuan, Taiwan; ³National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Department of Gastroenterology, Athens, Greece; ⁴National and Kapodistrian University of Athens, General Hospital of Athens "Hippokratio," 2nd Department of Internal Medicine, Athens, Greece
Email: gepapath@med.uoa.gr

Background and aims: In a previous multicenter cohort study including chronic hepatitis B (CHB) patients with mixed HBeAg status (89% Asians), there was little impact of ethnicity on HBsAg seroclearance during nucleos (t)ide analogue (NA) therapy (crude hazard ratio: 0.8, Hsu YC et al JID 2021), but the potential impact of ethnicity/race on HBsAg kinetics during NAs remains unclear. We assessed potential differences in HBsAg kinetics between Taiwanese and Greek HBeAg-negative CHB patients.

Method: Non-cirrhotic HBeAg-negative CHB patients (n = 806) from Taiwan (n = 541) and Greece (n = 265) receiving entecavir (ETV) or tenofovir (TDF) were recruited. Baseline host and viral characteristics and NA type were compared between those with and without rapid on-NA HBsAg decline (>0.5 log₁₀ IU/ml/year). Logistic regression identified predictors and a 1:1 propensity score matching for HBV genotypes (GT) B and C/D was performed for sensitivity analysis.

Results: Compared to the Greek, the Taiwanese cohort had greater proportion of males (81% vs. 68%, P < 0.001) and history of past treatment (63% vs. 41%, P < 0.001), increased utilization of ETV (75% vs. 42%, P < 0.001), higher ALT (192 vs. 63 U/L, P < 0.001) and HBV DNA levels (6.5 vs. 5.1 log₁₀ IU/ml, P < 0.001), lower HBsAg levels (3.2 vs. 3.5 log₁₀ IU/ml, P < 0.001) at NA onset, and shorter follow-up (3 vs. 3.9 years, P < 0.001). Multivariate logistic regression identified past treatment history [adjusted Odds Ratio (aOR): 2.03, P = 0.006], ALT > 5x ULN (aOR: 2.18, P = 0.003) and higher HBsAg levels at NA onset (aOR: 3.58, P < 0.001) as independent predictors for on-NA rapid HBsAg decline, while ethnicity/race did not reach statistical significance (aOR: 2.1, P = 0.07). Univariate analysis indicated that patients with GT-C (crude OR: 0.47, P = 0.072) or D (crude OR: 0.23, P < 0.001) compared to GT-B were less likely to experience on-NA rapid HBsAg decline. In the PS-matched cohort, adjusting for characteristic differences between GT-B vs. C/D patients, multivariate logistic regression showed that patients with HBV GT-C/D infection were less likely to have rapid on-NA HBsAg decline (aOR: 0.4, P = 0.02). The predominant impact of HBV GT on HBsAg kinetics occurred in the first year of NA therapy (GT-B vs. GT-C/D: HBsAg reduction: -0.35 vs. -0.12 log₁₀ IU/ml/year, P < 0.001), even after adjusting for ALT, HBV DNA, and HBsAg levels at NA onset. The cumulative incidence of on-

NA HBsAg loss was comparable between different ethnicity/race (log-rank test, P = 0.4) and HBV GTs (log rank test, P = 0.2).

Conclusion: On-NA HBsAg kinetics are mostly affected by HBV GT and baseline characteristics like high ALT and low HBsAg levels, but not by ethnicity/race. HBV GT influences HBsAg reduction primarily within the first year of NA therapy.

FRI-418

10-year clinical outcomes in chronic hepatitis B patients treated with tenofovir in The Gambia, West Africa

Erwan Vo Quang¹, Gibril Ndow², Sulayman Bah³, Rohey Bangura³, Lamin Bojang³, Bakary Dibba³, Sainabou Drammeh³, Alhagie Touray³, Kitabu Jammeh³, Isabelle Chemin⁴, Amie Ceesay³, Gavin Cloherty⁵, Umberto D'Alessandro³, Mark R. Thursz³, Yusuke Shimakawa⁶, Maud Lemoine³. ¹Medical Research Council Unit, London School of Hygiene and Tropical Medicine, Fajara, Gambia; ²Medical Research Council Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, The Gambia, Fajara, Gambia; ³Medical Research Council Unit The Gambia, London School of Hygiene and Tropical Medicine, Banjul, The Gambia, Fajara, Gambia; ⁴International Agency for Research on Cancer, Lyon, France, Lyon, France; ⁵Abbott USA, USA, United States; ⁶Institut Pasteur, Paris, France, Paris, France
Email: erwan.voquang@gmail.com

Background and aims: Effectiveness and safety of long-term tenofovir disoproxil fumarate (TDF) in people with chronic hepatitis B virus infection (CHB) has been inadequately documented in Africa. From the longitudinal PROLIFICA study, we evaluated the long-term clinical outcomes of CHB patients treated with TDF in The Gambia.

Method: In this prospective cohort study, we followed-up participants who were consecutively diagnosed with CHB without HCC between 2012 and 2015 in The Gambia. CHB participants eligible to treatment (EASL guidelines) were initiated on TDF, 300 mg daily. The primary outcome was the overall survival in untreated and treated patients.

Results: From December 2011 to October 2015 1, 117 treatment naïve CHB participants were recruited, including 141/1, 117 (12.6%) initiated on TDF. Treated patients were mainly males (84%) with baseline median age at 35 (IQR: 28–39), median Fibroscan 8.9 (7.0–14.0), including 54/121 (45%) cirrhosis, 3.0% and 7.2% of HCV or HDV coinfections, median HBV DNA 3, 474 (IQR: 142–263, 720) and eAg positive in 37/131 (28%). During a median follow-up of 6.8 (5.6–8.6) years, 62/1117 (4.3%) died of any cause, including 35/141 (24%) on TDF. Deaths were mostly driven by end-stage liver disease (87.5%) followed by HCC (12.5%). The 1-, 6- and 10-year cumulative survival probabilities in treated patients without cirrhosis, with compensated or with decompensated cirrhosis at baseline were 100%, 95% and 92%; 100%, 97% and 96%, 88%, 63% and 57%; respectively (p < 0.01). The mortality rate among non-cirrhotic patients on TDF was similar to that of untreated and ineligible patients (p = 0.28). Cirrhosis (HR: 8.3, 95%CI 1.6–42.7) and ascites (HR 4.7, 1.4–16.0) were independent predictive factors of mortality at baseline among patients on TDF. Proportion of treated patients with undetectable HBV DNA and ALT normalisation were 66% and 45% at year 6, 93% and 88% at year 10. 31/80 (38%) and 11/25 (44%) had significant liver fibrosis regression at year 6 (p < 0.01) and 10 (p = 0.04), including 17/25 (68%) and 5/6 (83%) of cirrhosis regression, respectively. Adherence to TDF was very good in most patients (70% and 87% at year 6 and 10, respectively). Kidney impairment on TDF was observed in only 2/138 (1.4%) patients and was comparable the rate 10 of 503 untreated CHB patients (2.0%) Bone mass analysis in treated and untreated patients is in progress.

Conclusion: In non-cirrhotic patients, TDF is associated with an excellent safety profile and an overall survival at 10 years, comparable to the survival observed in untreated CHB patients who are ineligible for AVT. The suboptimal survival among cirrhotic patients reflects the lack of early diagnosis of cirrhosis in Africa.

FRI-419

Epidemiological characteristics of hepatitis D virus infection in patients with hepatitis B related hepatocellular carcinoma

Tangner Talafu¹, Xinting Li¹, Li Yang¹, Rongjiong Zheng¹, Xiaobo Lu¹.
¹Xinjiang Clinical Research Center for Infectious Disease (Viral Hepatitis), Center for Infectious Disease and Hepatology of the First Affiliated Hospital of Xinjiang Medical University, Urumqi, China
 Email: xjykdluxiaobo@126.com

Background and aims: The objective of this study was to explore the seroepidemiological features of hepatitis D virus (HDV) infection among individuals diagnosed with HBV-associated primary hepatocellular carcinoma (HCC) at a singular medical center in Xinjiang.

Method: This study employed a single-center, cross-sectional analysis, enrolling 180 patients with HBV-associated HCC hospitalized between December 2021 to May 2023 at the Center for Infectious Disease and Hepatology of the First Affiliated Hospital of Xinjiang Medical University. All patients underwent Anti-HDV IgM, anti-HDV IgG and HDV Ag tests to investigate the epidemiological traits of co-infected HDV in HBV-associated HCC patients, as well as the correlation between HDV and HBV virologic and serologic markers.

Results: Out of the 180 patients, with a mean age of 56.67 ± 9.50 years and 156 (86.67%) being male, 23 (12.78%) were HDV seropositive (HDV-IgM and/or HDV-IgG and/or HDV-Ag) individuals. Epidemiological analysis of HDV seropositive patients indicated a mean age of 56.17 ± 12.90 years, with 19 (82.60%) being males, median ALT of 29 U/L and AST of 44.57 U/L. Vertical transmission accounted for 85% of HBV infections, with no history of intravenous drug use. Stratifying by HBV DNA loads revealed HDV seropositivity rates of 15.7%, 10.3% and 5.6% for HBV DNA <20 IU/ml, 20–2000 IU/ml, and >2000 IU/ml, respectively. Correlation analysis suggested an inverse trend between HDV seropositivity and HBV DNA levels ($p > 0.05$), that is the lower the level of HBV DNA, the higher the rate of HDV seropositivity. Grouping by HBsAg levels (HBsAg <0.05 IU/ml, 0.05–250 IU/ml and >250 IU/ml) showed HDV seropositivity rates of 4%, 7.7% and 18.9% respectively, with a significant positive correlation between HDV seropositivity and HBsAg levels ($p < 0.05$), that is the higher the level of HBsAg, the higher the HDV seropositivity rate. Analysis of disease duration, biochemical indices, and coagulation function and other laboratory indicators revealed no statistically significant differences between HDV seropositivity and negative patients ($p > 0.05$).

Conclusion: The seroprevalence of HDV among patients with HBV-associated HCC at a single center in Xinjiang was found to be 12.78%, indicating a notable prevalence. This underscores the importance of emphasizing the role of HDV in the etiology of hepatocellular carcinoma and suggests potential implications for the strategy of hepatocellular carcinoma prevention.

FRI-420

Serum HBsAg rather than HBV DNA reflects liver HBV transcript levels of hepatitis B patients treated by nucleoside analogues

Wenhua Zhang¹, Haitao Tang¹, Qinghua Lu², Tingxia Chao³, Haifang Cao², Hongfei Zhang⁴, Feng Ren⁵.
¹Gansu Wuwei Tumour Hospital, Wuwei, China; ²The 4th People's Hospital of Qinghai Province, Xining, China; ³Gansu Wuwei Tumour Hospital, Wuwei, China; ⁴Jumei Doctor Group Medical (Shenzhen) Co., Ltd, Shenzhen, China; ⁵Beijing Youan Hospital, Capital Medical University, Beijing, China
 Email: 925944468@qq.com

Background and aims: The therapeutic goal of CHB is to achieve a “functional” cure, which is characterized by sustained HBsAg loss and HBV DNA levels below the lower limit of detection. However, it is almost impossible to achieve sustained HBsAg loss with nucleoside analogues (NAs) treatment. It is poor treatment efficacy and low HBsAg conversion rate for antiviral treatment of CHB patients with high HBsAg levels, although serum HBV DNA levels were below the lower limit of detection or undetectable. Here, we evaluated serum HBsAg and serum HBV DNA, which is better for evaluating HBV

transcriptional activity in liver tissue of hepatitis B patients treated by NAs.

Method: This study was derived from the “Excellence” project-HBV cohort, which consisted of 20 CHB patients (male/11, female/9) with NAs (ETV/TDF/TAF) treatment for a median interquartile range (IQR) of 36 (4–240) months, whose aged 27–58 years and admitted to the hospital from May 2023 to October 2023. Liver histologic biopsy was performed immediately after admission. Intrahepatic HBV covalent closed loop DNA (cccDNA) was quantified by droplet digital PCR (ddPCR), and intrahepatic HBV DNA was quantified by quantitative real-time PCR (qRT-PCR). Intrahepatic HBV cccDNA and HBV DNA parameters were analyzed in relation to serum HBsAg and HBV DNA levels, respectively.

Results: Serum HBsAg levels of all CHB patients with antiviral treatment were greater than 1500 IU/ml, but serum HBV DNA were already at very low or undetectable levels. Interestingly, for CHB patients with no HBV DNA detection in serum, their liver tissues have high levels of HBV DNA (4.880 ± 0.894 , log₁₀ IU/ml) and HBV cccDNA (3.967 ± 0.695 , log₁₀ copies/μL) with significantly positive correlation ($r = 0.772$, $P < 0.0001$). Serum HBsAg level was positively correlated with intrahepatic HBV cccDNA level ($r = 0.673$, $P = 0.0011$), and positively correlated with intrahepatic HBV DNA level ($r = 0.728$, $P = 0.0003$). The serum HBsAg and serum HBeAg level had good correlation ($r = 0.618$, $P = 0.0037$), however, serum HBV DNA and serum HBeAg level were no correlated with intrahepatic HBV cccDNA level and intrahepatic HBV DNA level.

Conclusion: In CHB patients with NAs treatment, serum HBsAg rather than HBV DNA reflects liver HBV transcript levels of hepatitis B patients. It is serum HBsAg level, not HBV DNA level that may comprehensively reflect HBV replication activity and help evaluation of antiviral therapeutic efficacy.

FRI-423

Early treatment of patients with indeterminate HBV viraemia does not improve retention in care and risks overtreating patients who may spontaneously clear HBsAg

Sharon Macleod¹, Fiona Marra², Alison Boyle², Erica Peters³, Rachael Swann³, Ewan H. Forrest⁴, Stephen Barclay⁴.
¹NHS Greater Glasgow and Clyde, Glasgow Royal Infirmary, Pharmacy Department, Glasgow, United Kingdom; ²NHS Greater Glasgow and Clyde, Gartnavel General Hospital, Glasgow, United Kingdom; ³NHS Greater Glasgow and Clyde, Queen Elizabeth Hospital, Glasgow, United Kingdom; ⁴NHS Greater Glasgow and Clyde, Walton Liver Clinic, Glasgow Royal Infirmary, Glasgow, United Kingdom
 Email: sharon.macleod2@ggc.scot.nhs.uk

Background and aims: Current HBV treatment guidelines include recommendations to observe patients with indeterminate viraemia, and/or ALT elevations to establish their true phase of infection. Recent evidence suggests however that many patients persist in the indeterminate phase of infection, leaving the best course of action unclear. We sought to examine the outcomes of patients with indeterminate viraemia with regards to phase of infection, investigation, and initiation of treatment, along with HBsAg loss.

Method: Samples tested for HBV DNA in our health board with a unique patient identifier between 2009 and 2022 were identified from a virology database, and each individual's first and last HBV DNA identified. Viraemia was classed as indeterminate if between 2,000 iu/ml and 20,000 iu/ml and low or high if below or above this range respectively. Adults with indeterminate viraemia, and a minimum of 1 quantifiable viral load at 12 months or later underwent case note interrogation. Data was recorded on demographics, ALT, DNA, liver biopsy, treatment status, HBsAg loss and retention in care. Patients were considered retained in care if they attended their last appointment prior to December 2023, or if relevant discharge, death or transfer out of area. Patients were excluded if case note review demonstrated treatment prior to first recorded DNA.

POSTER PRESENTATIONS

Results: 26, 522 DNA samples relating to 3, 422 individuals were identified. Of these 1, 1615 had two samples ≥ 12 m apart (median 59 m, IQR 67), of which 236 (14.6%) were indeterminate (996 (61.7%) low 383 (23.7%) high). 14 indeterminate cases were excluded (13 prior treatment, 1 paediatric). Of the remaining 222, 145 (65.3%) were male, with a median age of 34. 30 (13.5%) also had indeterminate (1–2 \times ULN) ALT and 10 (4.5%) high ALT. 11 were born in the UK, with Asia (89) and Africa (67) the most common regions of origin. At 12 months low/indeterminate/high viral loads were seen in 96 (43.2%), 84 (37.8%) and 18 (9.9%) respectively, whilst 22 (9.9%) had commenced treatment. 24 (10.8%) underwent liver biopsy at some point during assessment, of whom 11 received treatment. At last assessment viral loads were high/indeterminate/low or undetectable in 11 (5) %, 61 (27.6%) and 93 (42.1%), including 15 patients (6.8%) who had HBsAg loss. 56 patients (25.3%) received treatment by end of follow-up, 28 within 18 months and 28 beyond. Retention in care was not influenced by starting treatment by 18 months (71.4% vs 69.6%, $p = 0.84$).

Conclusion: In this cohort 1:4 individuals with initial indeterminate DNA required treatment per current guidelines. Earlier treatment of those with indeterminate HBV DNA levels will simplify care and may avoid liver biopsy, though the minority underwent this. 42% of patients had low level viraemia at the end of follow-up including 6.8% with HBsAg loss who would be overtreated. Early treatment did not appear to influence retention in care.

FRI-424

Effectiveness of immunoprophylaxis for preterm infants of mothers having chronic hepatitis B virus infection: a retrospective study

Guanlun Zhou¹, Guorong Han¹, Yuhao Ju¹, Yan Chen¹, Chao Chen¹. ¹The Second Hospital of Nanjing, Nanjing, China
Email: gl270408@163.com

Background and aims: The long-term effectiveness of immunoprophylaxis for preterm infants delivered by mothers with hepatitis B virus (HBV) infection remains unclear. This study aimed to investigate the effectiveness and indicators of immunoprophylaxis in preterm infants.

Method: 2238 infants delivered by HBsAg-positive mothers were enrolled, including 175 preterm infants and 2063 full-term infants. Preterm infants were administered 10 μ g of hepatitis B vaccine immediately after birth and at one, two and seven months while full-term infants received vaccine immediately after birth and at one and six months. All infants were followed up till 24 months. Effectiveness of immunoprophylaxis in preterm infants was analyzed by comparing the dynamics of HBV mark (HBV-M) and responsible factors were investigated using multivariate regression analysis.

Results: The differences in the HBsAb titers between groups were not statistically significant at 7–12 and 24 months of age ($p > 0.05$), but the titers in the preterm group were lower relative to the full-term group. There were no significant differences ($p > 0.05$) between the two groups for medium-to-high responses of HBsAb at 7–12 and 24 months. Multivariate logistic regression analysis showed that Apgar score at one minute (2.687 [1.116, 6.472]) was a predictor of medium-to-high response of HBsAb at 7–12 month.

Conclusion: HBsAb titers in preterm infants delivered by HBV-infected mothers who were vaccinated following the “0–1–2–7” immunoprophylaxis protocol were similar to those in full-term infants, thereby indicating good outcomes. One-minute Apgar score could be used to predict HBsAb levels in preterm infants at 7–12 months of age after completion of the immunoprophylaxis regimen.

FRI-425

Hepatitis B core-related antigen (HBcrAg) in a prospective French hospital database on chronic hepatitis B (HBVbiomark)

Erwan Vo Quang¹, Stéphane Chevaliez¹, Scoazec Giovanna², Varaut Anne², Giuliana Amaddeo², Amal Boukraa², Mélanie Simoes²,

Anne Laure Mazialivoua², Alexandre Soulier¹, Valérie Ortonne¹, Olivia Garrigou¹, Jean-Michel Pawlotsky¹, Vincent Leroy², Patrick Ingiliz². ¹INSERM U955, Creteil, France; ²Hopital Henri-Mondor, Creteil, France

Email: patrick.ingiliz@aphp.fr

Background and aims: Hepatitis B core-related antigen (HBcrAg) is a composite marker consisting of HBcAg, HBeAg and p22cr, suggested to be used in clinical practice in order to predict hepatitis B virus (HBV) disease stages or outcomes. HBcrAg is a translational product of viral transcription, and may be used in addition to such as ALAT, viral load, HBeAg or quantitative HBsAg (qHBsAg) to characterize eAg-negative patients. Here, we assessed HBcrAg levels in a French mono-centric eAg-negative HBV database.

Method: HBVbiomark is a prospective cohort of HBV patients followed-up in the outpatient department of the Henri-Mondor Hospital in Créteil, France. After informed consent, patients clinical, virological and treatment data are captured on an annual basis, and blood samples are stored for investigation of novel biomarkers. HBcrAg is measured by chemiluminescence method using the automatic Lumipulse G600 II analyzer (Fujirebio Inc, Japan) according to the manufacturer's instructions. HBsAg-positive/HBeAg-negative subjects were classified according to EASL guidelines as: chronic hepatitis B (CHB), e-negative infection (ENI) and grey zone (GZ, -viral load >2000 IU/ml and normal ALT, or viral load <2000 IU/ml and elevated ALT).

Results: Since May 2023, 348 patients have been included and 233 were eAg negative. The median age is 46 years (IQR: 37–58), and 70% are male. 91% of patients were born outside France, most of which (63%) in sub-Saharan Africa. The median ALT level is 27 U/L, the median liver stiffness value is 5 kPa (IQR 4.3–6.2), the median HBV DNA level is 25 U/L (IQR 10–695 UI/ml), the median HBsAg level is 2746 IU/ml (583–11988 IU/ml) and the median HBcrAg level 2.5 (IQR 2.0–3.3) log U/ml. About half of the patients (44%) were on antiviral treatment. 90/233 (74.6%) were classified as ENI, 104/233 (45%) as CHB, and 39/233 (17%) as GZ. HBcrAg levels were 2.3, 2.75, and 2.6 log IU/ml in ENI, CHB, and GZ respectively ($p = 0.08$), and treatment duration did not change HBcrAg levels. Proportion of patients with HBcrAg levels above 3 log UI/ml was different across CHB, ENI and GZ, with 44%, 26% and 31%, respectively ($p = 0.03$). No correlation was found with HBV viral load and quantitative HBsAg levels.

Conclusion: HBcrAg may help to define disease stages more accurately, especially for the so-called grey zone in e-negative patients, and the inactive carrier state in patients from Sub-Saharan Africa. Our cohort will further study the relation of novel biomarkers and disease progression.

FRI-426

Comparing the impact of Interferon-based and direct-acting agents therapies on HBsAg seroclearance rates in patients with hepatitis B and hepatitis co-infection

Cheng Er Hsu¹, Yen-Chun Liu¹, Rachel Wen-Juei Jeng¹, Ya-Ting Cheng¹, Yi-Chung Hsieh¹, Wei Teng¹, Rong-Nan Chien¹, I-Shyan Sheen¹, Chun-yen Lin¹. ¹Chang Gung Memorial Hospital, Linkou Branch, Taiwan, Taoyuan, Taiwan
Email: rachel.jeng@gmail.com

Background and aims: The treatment approach for chronic hepatitis C (CHC) has shifted from interferon-based regimens (IFN) to direct-acting agents (DAAs) due to enhanced tolerance and increased sustained virological response (SVR) rates. While pegylated interferon remains a primary therapy for chronic hepatitis B, it is unclear whether HBsAg seroclearance rates in coinfecting HBV/HCV patients in an HBV-endemic country, where most HBV infections are acquired perinatally, are higher with IFN-based regimens compared to DAAs, which specifically target HCV. This study aims to compare HBsAg seroclearance rates in HBV/HCV coinfecting patients treated with IFN-based or DAA regimens.

Method: Retrospective analysis was conducted on two cohorts from Chang Gung Memorial Hospital, Linkou branch: the IFN-based CHC cohort (July 2002–January 2017) and the DAA CHC cohort (March 2015–December 2019). The study focused on CHC patients with a pre-therapy HBsAg seropositive status, including those with available follow-up HBsAg serostatus and achieved SVR. Cox regression analysis identified independent factors for HBsAg seroclearance. Propensity score matching (PSM) addressed heterogeneity between the IFN and DAA groups, adjusting for age, gender, ALT levels, and qHBsAg levels at start of anti-HCV treatment. Kaplan-Meier analysis and log-rank tests compared the cumulative HBsAg seroclearance incidence between the two groups.

Results: Among 356 HBV/HCV coinfecting patients achieving SVR, 130 received IFN-based treatment, and 226 received DAA treatment. The IFN group was younger age (51.3 vs. 59.9 years, $p < 0.001$), predominantly male (69% vs. 54%, $p = 0.0067$), and higher baseline ALT levels (89.5 vs. 50.0 U/L, $p < 0.001$), and longer follow-up (median: 10.3 vs. 4.3 years, $p < 0.001$), had comparable pretherapy HBsAg levels (185 vs. 103 IU/ml, $p = 0.17$). During follow-up, 57 IFN-based and 27 DAA patients achieved HBsAg loss. The 5-year cumulative HBsAg seroclearance rate was numerically higher in IFN than DAA (19% vs. 12%, $p = 0.194$). Multivariate Cox regression identified pre-therapy qHBsAg < 100 IU/ml (aHR: 2.85, $p < 0.001$) and post-therapy qHBsAg < 100 IU/ml (aHR: 3.54, $p < 0.001$) as independent factors for HBsAg loss, while IFN treatment did not reach significance (crude HR: 1.12, $p = 0.67$). After PSM (59 patients in each arm), age, male proportion, and pre-therapy HBsAg level were comparable. The 5-year cumulative HBsAg seroclearance was numerically higher in the IFN arm (28% vs. 13%, $P = 0.172$) but did not achieve statistical significance.

Conclusion: In an HBV-endemic country with HBV/HCV coinfection, IFN-based therapy did not significantly increase the HBsAg loss rate compared to the DAA regimen. This could be attributed to the initially low HBsAg levels in these patients. Lower HBsAg levels at the beginning or end of anti-HCV treatment are independent factors for post-anti-HCV treatment HBsAg loss.

FRI-427

Chronic hepatitis delta with normal ALT and hepatitis D viremia: unravelling its natural history

Muge Ozari Gulnar¹, Habiba Kamal², Adriana Palom³, Sena Arici⁴, Rafael Esteban⁵, Esra Tunç⁶, Onur Keskin⁷, Ramazan Idilman⁴, Maria Buti⁸, Soo Aleman⁹, Cihan Yurdaydin¹⁰. ¹Koc University School of Medicine, Department of Gastroenterology, Istanbul, Turkey; ²Dept of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden; ³Vall d'Hebron University Hospital, Barcelona, Spain; ⁴Ankara University School of Medicine, Ankara, Turkey; ⁵Hospital Universitari Vall d'Hebron, Barcelona, Spain; ⁶Ankara University School of Medicine Department of Gastroenterology, Ankara, Turkey; ⁷Hacettepe University School of Medicine, Ankara, Turkey; ⁸Hospital Universitari Vall d'Hebron, Barcelona, Spain; ⁹Department of Infectious Diseases, Karolinska University Hospital/Karolinska Institutet, Stockholm, Sweden; ¹⁰Koc University School of Medicine, Department of Gastroenterology, Istanbul Email: muge.ozari@gmail.com

Background and aims: Chronic hepatitis delta (CHD) represents the most severe form of chronic viral hepatitis and the main cause of liver-related mortality due to suboptimal therapy. However, CHD may run a less severe course than in the past (Rosina et al, Gastro 1999, Kamal et al, Hepatology 2020). We had previously described patients with persistent normal ALT and hepatitis D viremia (PNAV) (Arici et al, EASL 2021). The aim of the current study was to increase the size of this patient population and to unravel the natural history of PNAV.

Method: PNAV were arbitrarily defined as patients with normal ALT and hepatitis D viremia on at least three determinations, 3 to 12 months apart within a duration of 2 years among patients who had never received interferon and/or bulevirtide based treatment for CHD. Such patients have been collected between 2014–2023 from the

databases of 2 academic hospitals in Turkey, one in Spain and one in Sweden. A total of 44 PNAV are described. Follow-up was 18 months to 12 years.

Results: The centers in Sweden, Spain and two centers in Turkey contributed a total of 20, 12, 8 and 4 patients from database cohorts of 157, 60, 250 and 50, respectively. Cirrhosis was reported in 12 patients based on imaging studies, and FibroScan or liver biopsy. Endoscopy was performed in 20 patients, small varices were detected in one case only. On long term follow-up two type of patient scenarios evolve: one group of patients continue with normal ALT and viremia, in the other group HDV RNA levels tend to decrease or even became undetectable. The 2 groups did not differ in terms of age, gender, ALT, AST, GGT or platelet count (214 ± 86 [$x \pm SD$] [$n = 25$] vs. 237 ± 81 [$n = 18$], $p = 0.372$) but patients displaying low or undetectable HDV RNA levels (< 1000 IU/ml) appear to have significantly lower qHBsAg levels (7378 ± 5722 vs. 987 ± 1402 , $p = 0.0073$). HDV RNA levels were similar (3.60 ± 1.11 vs. 4.23 ± 1.43 IU/ml). Liver biopsy was available in 10 patients. Histologic activity index and fibrosis stage were lower in PNAVs vs controls (8 [3–13] vs 10 [8–14] and 2 [0–4] vs 3 [2–6], $p = 0.05$ and $p = 0.014$, respectively). In the PNAV group, 2 patients had fibrosis stage 3 and 4 according to Ishak et al and one patient had cirrhosis on biopsy. Three additional patients had clinical or radiologic evidence of cirrhosis. On long-term follow-up patients normal ALT persisted. HDV RNA became undetectable in one patient.

Conclusion: The study suggests that a subgroup of CHD patients present with normal ALT and hepatitis D viremia. The proportional weight of this subgroup in chronic hepatitis D cohorts needs careful assessment. PNAV do not necessarily imply milder disease and advanced fibrosis/cirrhosis may be observed, though clinically significant portal hypertension appears to be rare. Further, 18 (40%) patients developed low levels of viremia and even cleared HDV. The role of qHBsAg levels to predict this latter group needs serious consideration.

FRI-428

Evaluating the effectiveness and safety of tenofovir alafenamide fumarate for preventing mother-to-child transmission of hepatitis B virus

Malipati Aierkenjiang¹, Li Yang², Xiaofeng Sun³, Xiaobo Lu⁴.

¹Infectious Disease and Hepatology No.1 Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; ²Infectious Disease and Hepatology Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; ³Infectious Disease and Hepatology No.1 Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China; ⁴Infectious Disease and Hepatology Department, The First Affiliated Hospital of Xinjiang Medical University, Urumqi, China

Email: 387663581@qq.com

Background and aims: This investigation addressed the paucity of data on tenofovir allafenamide fumarate's (TAF) utility in preventing mother-to-child transmission (MTCT) of hepatitis B virus (HBV) among infected pregnant women. The study's purpose was to assess the effectiveness and safety of both TAF and tenofovir disoproxil fumarate (TDF) in preventing HBV MTCT.

Method: This single-center retrospective study totally enrolled 97 HBV-infected pregnant women with HBsAg-positive, HBeAg-positive and HBV DNA levels exceeding 200, 000 IU/ml. Participants received treatment with either TAF or TDF at 18–24 weeks of gestation at the Center for Infectious Diseases and Hepatology Department of the First Affiliated Hospital of Xinjiang Medical University from September 2018 to September 2021, Follow-up extended to 7 months postpartum. Standardized immunoprophylaxis was administered to infants within 12 hours of birth and at 1 and 6 months of age. The primary end point was the safety of mothers and infants throughout the treatment and follow-up, with secondary end points focusing on the MTCT rate at 7 months postpartum and virologic decline.

POSTER PRESENTATIONS

Results: TAF was administered to 43 pregnant women, while TDF was given to 54; there were 43 and 54 live-born infants respectively, with all mothers and infants completing the 7-month follow-up. After delivery, 87 subjects continued TAF or TDF treatment, and both groups were well-tolerated, without treatment discontinuation due to adverse events. The primary adverse events were puerperal anemia (23%) in the TAF group and perinatal rupture of membranes (16%) in the TDF group, unrelated to the therapeutic agents. Laboratory tests showed no alanine transaminase (ALT) flares during treatment and follow-up. No congenital malformations or defects were reported in infants at birth, and their growth parameters remained within the normal range at 7 months of age, no statistically significant differences were observed between the TAF and TDF groups ($P > 0.05$). Maternal HBV DNA levels exhibited a significant reduction from baseline at delivery, decreasing from 6.44 ± 0.88 to 3.33 ± 1.14 IU/ml in the TAF group, and from 6.57 ± 0.76 to 3.77 ± 0.95 IU/ml in the TDF group, with no statistically significant distinction in the magnitude of reduction between the group ($P > 0.05$). Infants from both groups tested negative for HBsAg, HBeAg, and HBV DNA at 7 months, displaying no statistical variance between the two groups ($P > 0.05$).

Conclusion: The effectiveness and safety of TAF in preventing mother-to-child transmission among HBV-infected pregnant women was similar to that of TDF. This was accompanied by a favorable safety and tolerability profile, and both groups achieved 0% HBV MTCT rate. These findings propose TAF as a viable option for future use in the prevention of mother-to-child transmission of HBV.

FRI-429

Detectable HDV RNA is associated with worse outcome in patients infected with HBV and HDV: results from a meta-analysis

Jackie Bitton¹, Laura Weichselbaum², Christophe Moreno², Pierre Deltenre^{2,3}. ¹Clinique Saint-Luc, Bouge, Belgium; ²CUB Hôpital Erasme, Brussels, Belgium; ³Clinique St-Luc, Bouge, Belgium
Email: pierre.deltenre01@gmail.com

Background and aims: Patients with chronic hepatitis B who are co- or super-infected with hepatitis delta virus (HDV) usually have a more aggressive liver disease than mono-infected hepatitis B virus (HBV) patients. However, whether HDV RNA status is associated with increased risk of liver events in patients with both HBV and HDV infection has not been precisely assessed. We aimed to synthesize the available evidence on whether HDV RNA status is associated with an increased risk of liver-related events in patients infected with HBV and HDV.

Method: Meta-analysis of trials evaluating liver-related events in patients with HBV and HDV infection according to the presence or the absence of detectable HDV RNA. Random effects model was used to obtain a summary estimate of primary outcomes among patients who had detectable HDV RNA vs. those who had undetectable HDV RNA. Differences between groups were expressed as odds ratios (ORs) with 95% CIs. Primary end points were the development of cirrhosis, hepatic decompensation, hepatocellular carcinoma and death or liver transplantation. Heterogeneity was assessed using Cochran's Q test and the I^2 statistic.

Results: Six studies with 1391 HBsAg and HDV antibody positive patients were included. 1089 patients had detectable HDV RNA and 302 had undetectable HDV RNA. Median age ranged between 30 and 49 years and 66% of patients were males. Age and sex ratio did not seem to differ between patients who had detectable HDV RNA and those who had undetectable HDV RNA. The median follow-up ranges between 36 and 233 months. Data on cirrhosis was available for 647 patients, data on decompensation for 702 patients, data on hepatocellular carcinoma for 770 patients and data on death or liver transplantation for 773 patients. Compared to patients with undetectable HDV RNA, patients with detectable HDV RNA had a higher risk of cirrhosis (OR = 4.3, 95% CI = 2.1–8.8, $p < 0.01$) with high heterogeneity between studies ($p = 0.01$, $I^2 = 71\%$), a higher risk of decompensation (OR = 3.2, 95% CI = 1.7–6.1, $p < 0.01$) with moderate

heterogeneity between studies ($p = 0.15$, $I^2 = 43\%$), a higher risk of hepatocellular carcinoma (OR = 2.0, 95% CI = 1.2–3.6, $p = 0.01$) with low heterogeneity between studies ($p = 0.2$, $I^2 = 27\%$) and a higher risk of death or liver transplantation (OR = 3.9, 95% CI = 2.7–5.6, $p < 0.01$) with no heterogeneity between studies ($p = 0.6$, $I^2 = 0\%$).

Conclusion: Patients infected with HBV and HDV who have detectable HDV RNA have a higher risk of liver disease progression including death or the need for liver transplantation than patients with undetectable HDV RNA.

FRI-430

Efficacy and safety of Tenofovir Amibufenamide in the treatment of chronic hepatitis B: a real-world multicenter clinical study

Yaping Li¹, Hongmei Zu², Yongmei Lin³, Guoe Gou¹, Xiaohong Gao⁴, Guang-Hua Xu⁴, Dandan Cui¹, Shuangsoo Dang¹. ¹The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; ²The Fourth People's Hospital of Qinghai Province, Xining, China; ³Hanzhong 3201 Hospital, Hanzhong, China; ⁴Affiliated Hospital of Yan'an University, Yan'an, China
Email: dang212@126.com

Background and aims: The clinical profile of Tenofovir Amibufenamide (TMF) in patients with chronic hepatitis B (CHB) requires further clarification. This study evaluates the real-world effectiveness and safety of TMF and compares it to tenofovir disoproxil fumarate (TDF) in a CHB cohort.

Method: In this multicenter, prospective, real-world cohort study, we recruited 183 eligible patients with CHB who attended the outpatient clinic of the Department of Infection of the 4 sites from August 2021 to August 2022. 183 subjects were stratified into TMF ($n = 94$) and TDF ($n = 89$) groups, as well as treatment-naïve (TN) and treatment-experienced (TE) subgroups. We monitored virological response (VR, defined as HBV DNA < 20 IU/ml), alanine transaminase (ALT) normalization rates, renal function markers, and lipid profiles.

Results: In the TN cohort, virological response (VR) rates at weeks 24 and 48 for the TMF group were 42.86% and 90.48%, respectively, compared to 60.00% and 83.33% for the TDF group. The differences in VR rates between TMF and TDF were not statistically significant ($\chi^2 = 3.615$, $p = 0.057$; $\chi^2 = 1.386$, $p = 0.239$). ALT normalization rates for the TMF group were 84.85% and 90.91% according to local laboratory standards, and 56.82% and 70.45% per AASLD 2018 standards. Corresponding rates for the TDF group were 92.59% and 96.30% (local laboratory standards), and 61.90% and 78.57% (AASLD 2018 standards). These differences were also not statistically significant ($\chi^2 = 0.230$, $p = 0.631$; $\chi^2 = 0.744$, $p = 0.388$). Among the treatment-experienced (TE) group, VR rates at weeks 24 and 48 were 65.71% and 82.86%, respectively. The ratios of ALT normalization for the TE group based on local laboratory standards were 86.67% and 93.33%, and according to AASLD 2018 standards, they were 66.67% and 76.67%. The TE group showed a statistically significant difference in ALT normalization following AASLD 2018 standards ($z = -2.822$, $p = 0.005$). VR rates for high-level viremia were similar between TMF and TDF groups ($\chi^2 = 1.635$, $p = 0.201$; $\chi^2 = 0.601$, $p = 0.438$), however, the TMF group showed a more marked reduction in viral load after 24 weeks. Additionally, TMF was associated with improved renal safety over TDF, with no significant difference observed in blood lipid levels between the two treatments.

Conclusion: TMF is comparable to TDF in the efficacy of CHB treatment with no adverse impact on renal function or lipid levels. For TE patients, transitioning to TMF from other antiviral therapies does not compromise antiviral efficacy.

FRI-431

The underestimated burden of hepatitis D among people living with chronic hepatitis B in the Gambia

Email: erwan.voquang@gmail.com

Background and aims: Hepatitis Delta virus (HDV) infection and its clinical impact in people living with chronic hepatitis B virus infection (CHB) have not been well documented in Africa. From a large-scale population-based and hospital-based cohort of CHB patients, we assessed the long-term clinical outcomes of CHB patients with positive HDV serology in The Gambia.

Method: We analyzed CHB patients who were prospectively enrolled in the PROLIFICA cohort study in The Gambia following a large-scale community- and blood bank-based screening intervention and new referral of CHB diagnosis to our liver clinic. All participants had a comprehensive liver assessment including fasting Fibroscan, HBV DNA measurement (GeneXpert, Cepheid) and HDV serology (Diasorin, Italy). The primary end point was the survival probability, and the secondary end point was the proportion of patients who had liver disease progression (≥ 1 stage increase by Fibroscan compared to baseline).

Results: From November 2012 to April 2024, 3, 074 CHB participants were recruited and 2, 504 were screened for HDV. At enrolment, median age was 33 (IQR: 32–45) and 68/2, 504 (12.6%) patients were tested positive for HDV. HDV-positive patients were mainly male (72%), baseline median age 38 (IQR: 32–50), median HBV DNA 176 (10–1, 732), median Fibroscan 8 kPa (5–28), including 34/80 (42.5%) and 17/86 (20%) with cirrhosis and HCC at enrolment, respectively; 6.0% and 3.5% were coinfecting with HIV and HCV. Completion of HDV analysis and genotyping are in progress. Multivariate analysis identified positive HDV serology, male sex, HBeAg positivity, HBV DNA >2000 IU/ml and APRI >2 as risk factors associated with cirrhosis (odds ratio: 8.2 (95%CI: 4.1–16.1, $p < 0.01$; odds ratio: 2.6 (CI: 1.6–4.2, $p < 0.01$; odds ratio: 2.6 (CI: 1.4–4.5, $p < 0.01$; odds ratio: 2.4 (CI: 1.6–3.6); $p < 0.01$; odds ratio: 39.4 (CI: 23.2–70.0); $p < 0.01$, respectively). Of 2, 504 patients, 1, 466 patients (58.5%) attended at least 2 follow-up visits. During a median follow-up of 6.0 (range: 2.1–7.5) years, 72 (4.9%) of the 1, 466 patients died of any cause. The 1-, 5- and 7-year cumulative survival probabilities were lower in HDV positive patients (92%, 84%, 84%, respectively) compared to HDV-negative participants (99%, 96% and 94%) ($p < 0.01$). In the whole cohort of CHB patients, age >40 years (HR 8.90, 2.67–29.71), positive HDV serology (HR 6.42, 2.16–19.14) and HCC (hazard ratio [HR] 27.07, 95% CI 9.25–79.24), were independent predictive factors of overall mortality. Compared to HDV-negative patients, development of cirrhosis but not liver fibrosis progression was more frequently observed in HDV-positive patients ($p < 0.02$).

Conclusion: Positive-HDV serology is frequently observed in individuals living with CHB in The Gambia and is associated with a poor

prognosis, highlighting urgent efforts for screening and care of HDV infection in Africa.

FRI-432

The concentration of HDV-RNA correlates with the probability of developing clinical events in patients with chronic hepatitis D

Adriana Palom^{1,2}, Sergio Rodriguez-Tajes^{2,3}, Ariadna Bono⁴, Antonio Madejón⁵, Ariadna Rando-Segura⁶, Sabela Lens^{2,3}, Marina Berenguer^{2,4}, Francisco Javier Garcia-Samaniego⁵, Juan Carlos Ruiz-Cobo¹, Ángela Carvalho-Gomes^{2,4}, Elena Vargas-Accarino⁷, Mar Riveiro Barciela^{1,2}, Rafael Esteban¹, Maria Buti^{1,2}. ¹Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; ²Centro de Investigación Biomédica en Red en Enfermedades Hepáticas y Digestivas, Madrid, Spain; ³Liver Unit, Hospital Clínic de Barcelona, IDIBAPS, Barcelona, Spain; ⁴Hepatology and Liver Transplant Department, Hospital Universitario y Politécnico La Fe, Valencia, Spain; ⁵Liver Unit, Hospital Universitario La Paz, IdiPAZ, Madrid, Spain; ⁶Microbiology Department, Clinical Analysis Laboratory, Hospital Universitari Vall d'Hebron, Barcelona, Spain; ⁷Liver Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain
Email: mariabutiferret@gmail.com

Background and aims: In patients with hepatitis D, the presence of HDV-RNA in serum is associated with disease progression and the development of clinical events. However, it has not been established whether serum HDV-RNA concentrations could predict clinical events, as is the case with hepatitis B. Our aim was to evaluate the relationship between HDV-RNA concentrations and the risk of developing liver events.

Method: Multicenter retrospective-prospective study including all adult anti-HDV positive patients followed for more than 1 year. HDV-RNA was quantified in an initial sample using an in-house PCR technique with a lower limit of detection (LLD) of 600 IU/ml in a centralized laboratory. Patients were visited every 6 months as per normal practice, and clinical events (decompensation, hepatocellular carcinoma, liver transplant, or liver-related death) were collected during follow-up.

Results: A total of 151 subjects were included; 60.9% male, median age 44 (IQR 36–52) years, all HDV untreated, HDV-RNA 15, 000 (IQR 0–518, 000) IU/ml, ALT 48 (IQR 29–87) IU/ml, and 32 (21%) with liver cirrhosis at inclusion. During a median follow-up of 5.5 (2.2–7.0) years, 25 patients (16.5%) experienced at least one clinical event. Baseline HDV-RNA levels were stratified based on a 1-log increase from the LLD of 600 IU/ml. The studied groups were: <600 IU/ml, between 600–6, 000, >6, 000–60, 000, >60, 000–600, 000, and >600, 000 IU/ml, and clinical events were observed in 4% (1/51), 12% (3/18), 20% (5/19), 24% (6/34), and 40% (10/29) of the patients, respectively ($p = 0.003$). Therefore, HDV-RNA concentrations were positively correlated to the presence of clinical events ($p < 0.001$). However, the rate of subjects with normal ALT was negatively correlated with the HDV-RNA concentrations ($p < 0.001$): 82.4% (42/51), 47.1% (8/17), 33.3% (6/18), 26.5% (9/34), and 21.4% (6/28).

When clustering groups comparing those with HDV-RNA between 600–600, 000 IU/ml and those with HDV-RNA >600, 000 IU/ml, the first group was less likely to present clinical events than the latter (14/71 vs 10/29) ($p = 0.097$). Among the 69 patients without liver cirrhosis, no differences in clinical events were observed between patients with HDV RNA 600–600, 000 vs >600, 000 (5/50 vs 4/19, $p = 0.203$) or normal ALT vs increased ALT (19/49 vs 5/19, $p = 0.250$). From the 24 patients with detectable HDV RNA without cirrhosis and normal ALT, those with 600–600, 000 IU/ml presented less clinical outcomes than those with >600, 000 IU/ml (0/19 vs 2/5) ($p = 0.036$).

Conclusion: The initial concentrations of HDV-RNA positively correlate with the development of clinical events, so their quantification would help predict the risk of clinical outcomes during subsequent follow-up. Moreover, in non-cirrhotic patients with normal ALT, those with initial HDV-RNA levels <600, 000 IU/ml are less likely to present clinical events than those with higher viraemias.

POSTER PRESENTATIONS

FRI-433

Metabolic dysfunction-associated steatotic liver disease is not independently associated with complete response to oral antiviral treatment in chronic hepatitis B

Juseok Lee¹, Byung Seok Kim¹, Changhyeong Lee¹, Jeong Eun Song¹.
¹Department of Internal Medicine, Daegu Catholic University School of Medicine, Daegu, Korea, Rep. of South
Email: ssong3004@naver.com

Background and aims: The impact of dysfunction-associated steatotic liver disease (MASLD) on treatment response following nucleos (t)ide analogue (NA) treatment for chronic hepatitis B (CHB) patients has not been clearly elucidated. The aim of this study is to investigate the impact of MASLD on complete viral response (CVR) and biochemical response in CHB patients who received NA treatment.

Method: We retrospectively recruited CHB patients receiving NA therapy from January 2014 to December 2020. CHB patients with decompensated cirrhosis or hepatocellular carcinoma were excluded. All patients were divided into CHB group and CHB with MASLD group according to MASLD diagnostic criteria. Therapeutic response related data were recorded and compared at multiple time points. Kaplan-Meier and Cox regression analyses were utilized to estimate the impact of MASLD on complete virological response (CVR).

Results: A total of 460 patients were enrolled (356 CHB without MASLD, 104 CHB with MASLD). The majority of patients were male (55.3%) and HBeAg-positive (55.2%). In comparison to non-MASLD patients, those with MASLD were more likely to be HBeAg-positive (65.4% vs. 52.2%, $p=0.018$), have hypercholesterolemia (22.9% vs. 12.5%, $p=0.009$), and present with a higher mean HBV DNA titer (6.56 ± 1.45 vs. 6.26 ± 1.47 , $p=0.064$). They also had a higher mean BMI (25.3 ± 3.4 vs. 22.9 ± 4.5 kg/m², $p < 0.001$) at baseline. Both groups achieved similar rates of ALT normalization (MASLD vs non-MASLD; 100% vs 99.7%, $p=0.588$), and HBsAg seroclearance (2.9% vs 3.7%, $p=0.707$) during the follow-up of up to 65 months. However, MASLD group had lower cumulative rates of CVR at week 96, compared with non-MASLD patients (81.1% vs 91.3%, $p=0.001$). In multivariate analyses, MASLD was not independently associated with CVR outcomes, but higher baseline HBV DNA and HBeAg positivity at baseline was negatively associated with achieving CVR.

Conclusion: The presence of MASLD did not negatively affect CHB treatment outcomes of complete virologic response or biochemical response.

FRI-434

High levels of anti-HBc are associated with higher rates of immune control after 48 weeks of treatment with PegIFN alfa-2a in patients with HBeAg-positive chronic hepatitis B

Maria Pfefferkorn¹, Simon Handrick¹, Melanie Maier², Cynthia Wat³, Thomas Berg¹, Florian van Bömmel¹.
¹Division of Hepatology, Department of Medicine II, Leipzig University Medical Center, Leipzig, Germany; ²Institute of Medical Microbiology and Virology, Leipzig University Medical Center, Leipzig, Germany; ³Roche Products Ltd, Welwyn, United Kingdom
Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: The clinical relevance of quantitative antibody levels to HBV core antigen (anti-HBc) as a new biomarker for chronic hepatitis B (CHB) was investigated, but observations on the relationship between anti-HBc levels and treatment response were contradictory. We aimed to investigate the association of anti-HBc levels with other HBV biomarkers and with treatment response to PegIFN alfa-2a.

Method: A total of 132 patients with HBeAg-positive chronic hepatitis B treated with 180 mg/week PegIFN alfa-2a for 48 weeks in three prospective multicenter studies (WV16240, WV16241 and WV19432; Hoffmann-La Roche) were retrospectively analyzed. Patients were analyzed according to week 72 treatment response in three different subgroups: I) patients with ($n=63$) or without ($n=69$)

serological response (SR; defined by HBeAg SC), II) patients with ($n=69$) or without ($n=69$) virological response (VR; HBV DNA levels <2000 IU/ml) and III) patients with ($n=50$) or without ($n=82$) combined response (HBeAg SC and HBV DNA levels <2000 IU/ml). Levels of anti-HBc were measured in samples collected at BL, week 12, 24, 48, and 72 using the anti-HBc II Abbott Architect system and the WHO anti-HBc standard.

Results: Patients with anti-HBc titers >4.0 log IU/ml at baseline had in comparison to patients with anti-HBc titers <4.0 log IU/ml a higher chance of achieving SR (59.1% vs. 43%) VR (72.7% vs. 38.2%) and CR (54.5% vs. 28.0%) while significantly lower probabilities (0% for SR, 28.6% for VR and 0% for CR) were demonstrated for low anti-HBc titers at BL (<2.0 log IU/ml). Interestingly, considering the threshold of 2.5 log IU/ml anti-HBc at BL, in patients with higher anti-HBc (>2.5 log IU/ml at BL) HBV RNA levels were significantly lower at week 48 and 72 (5.4 vs. 7.3 logcp/ml at week 72; $p < 0.001$), respectively.

Conclusion: In line with previous studies, HBeAg-positive patients benefit from higher anti-HBc levels at the beginning of PegIFN alfa-2a therapy and low levels (<2.0 log IU/ml) of anti-HBc might be a marker for a low immune response. The association of anti-HBc levels and response to treatment needs to be investigated for other treatments for chronic hepatitis B.

FRI-435

Serological and nucleic acid testing laboratory screening rates for hepatitis delta virus among adult patients in the United States

Robert Wong^{1,2}, Robert G. Gish³, Chong Kim⁴, Gary Leung⁵, Ira Jacobson⁶, Joseph K. Lim⁷, Marvin Rock⁴.
¹Stanford University School of Medicine, Stanford, United States; ²VA Palo Alto Healthcare System, Palo Alto, United States; ³Hepatitis B Foundation, Doylestown, United States; ⁴HEOR-Global Value and Access, Gilead Sciences, Inc., Foster City, United States; ⁵RWE-Epidemiology, Gilead Sciences, Inc., Foster City, United States; ⁶NYU Grossman School of Medicine, New York, United States; ⁷Yale University School of Medicine, New Haven, United States

Email: chong.kim9@gilead.com

Background and aims: Limited data exist regarding hepatitis delta virus (HDV) testing patterns. This study investigated real-world HDV laboratory screening and follow-up nucleic acid testing (NAT) rates among adult patients in the United States (US).

Method: Quest Diagnostics national laboratory data were used to identify US adults who completed at least one anti-HDV test without prior HDV RNA (RNA) testing from 1/1/2015 to 31/12/2022, in order to describe patterns of follow-up RNA testing and repeat anti-HDV testing. More specifically, among patients who tested positive for anti-HDV (anti-HDV-pos), we: a) identified the proportion of patients who completed follow-up RNA testing; b) examined results of RNA testing from patients who completed two rounds of follow-up RNA testing; and c) identified the proportion of patients who completed follow-up anti-HDV testing and had anti-HDV pos or anti-HDV negative (anti-HDV-neg) results.

Results: A total of 49, 272 patients completed anti-HDV testing without prior RNA testing, among whom 917 (1.9%) then completed an RNA test. Among 908 anti-HDV-pos patients, 268 (29.5%) completed follow-up RNA testing, of whom 95 (35.4%) had detectable RNA. Among the anti-HDV-pos patients with detectable RNA, a subsequent 51 (53.7%) patients had at least one additional RNA test, of whom 47 (92.2%) had detectable RNA and 4 (7.8%) had undetectable RNA. Among the 173 anti-HDV-pos patients with undetectable RNA, a subsequent 41 (23.7%) patients had at least one additional RNA test. Among 48, 364 patients who first tested negative for anti-HDV, 649 patients completed follow-up RNA testing, of whom 5 (0.8%) had detectable RNA. Moreover, of the 908 patients who were anti-HDV-pos on their initial anti-HDV test, 227 (25%) completed a second anti-HDV test of whom 127 (55.9%) tested positive and 100 (44.1%) tested

negative. All 4, 134 anti-HDV-neg patients who completed a second anti-HDV test remained negative.

Conclusion: Analyses of laboratory data from 2015 to 2022 showed that among anti-HDV-pos patients, follow-up HDV RNA testing rates are suboptimal. These data emphasise the utility and importance of NAT testing following anti-HDV results.

FRI-436

Are healthcare professionals appropriately screening for hepatitis delta virus in patients with chronic hepatitis B? Results from an interactive decision support app

Sarah Anderson¹, Jacqueline Meredith¹, Zachary Schwartz¹, Maria Buti². ¹Clinical Care Options, Reston, United States; ²Hospital Universitario Vall d'Hebron, CIBEREHD del Instituto Carlos III, Madrid, Spain, Barcelona, Spain
Email: sanderson@clinicaloptions.com

Background and aims: Patient variables that inform hepatitis B virus (HBV) and hepatitis delta virus (HDV) treatment candidacy and selection are complex and interconnected. In deciding whether and how to treat or monitor HBV, healthcare professionals (HCPs) must consider variables including HBeAg, HBV DNA, ALT, fibrosis, bone and renal alterations. In addition, EASL guidelines recommend that *all* people with HBV should be screened for HDV. To aid HCPs in aligning their management decisions with practice guidance, we developed an interactive decision support tool: an app called *Hep B Consult*. In this analysis, we used app results to examine whether HCPs who wanted to follow the EASL guidelines were appropriately working up patients for HBV and HDV.

Methods: In March 2023, Clinical Care Options (CCO) released the *Hep B Consult* app, available as a mobile app and on our website platform. The app enables HCPs to enter patient variables—if known—related to HBV and HDV infection. After the HCP specifies their intended approach, the app presents management recommendations specific to that patient case based on HCP-selected AASLD, APASL, or EASL practice guidance. To determine whether HCPs looking for EASL guidance were properly working up patients with HBV infection and screening for HDV according to EASL guidelines, we examined cases entered between March 3, 2023, and December 8, 2023. In cases where these HCPs marked any patient variables as “unknown” (HBeAg, HBV DNA, ALT, fibrosis, bone and renal alterations, HDV antibodies, HDV RNA), we considered the HCP’s workup incomplete. We measured how often HCPs had an incomplete workup and which variables HCPs failed to include.

Results: During the study period, 206 HCPs entered 419 cases after choosing EASL as their preferred HBV guidance. Of the cases entered by HCPs, most were entered by physicians (72.3%), followed by advanced practice nurses (2.4%), and pharmacists (1.2%). Of these cases entered by HCPs who identified their country (n = 212), 61.3% (n = 130) were entered by HCPs from Europe. The highest proportion of cases were entered by HCPs from the United Kingdom (20.8%), followed by Italy (8.0%) and Portugal (6.1%). None of the 419 cases entered was missing HBeAg, HBV DNA, ALT, fibrosis assessment, or bone or renal data. However, *HDV antibodies* were not screened in 25.2% (106/419) of cases. Of the cases entered by HCPs from European countries, HDV antibodies were not screened in 14.6% (19/130). Of the 78 cases where the patient was HDV antibody positive, 8.9% did not have follow-up screening for *HDV RNA*.

Conclusion: HCPs who used the *Hep B Consult* app to enter a patient case demonstrated a comprehensive patient workup *with the exception of HDV status*. This behavior is not aligned with the EASL HDV guidelines, which recommend screening all people who are HBsAg positive for HDV at least once. HCPs need education on the importance of screening all people with HBV for HDV.

FRI-437

Poor Performance of FIB-4 in Fibrosis Prediction for Chronic Hepatitis B Patients with Metabolic Dysfunction-Associated Liver Disease in Daily Clinical Practice

Fadi Abu Baker¹, Saif Abu Mouch¹, Dorin Nicola¹, Randa Taher¹.
¹Technion Faculty of Medicine, Haifa, Israel
Email: Fa_fd@hotmail.com

Background and aims: The coexistence of chronic hepatitis B (CHB) and metabolic dysfunction-associated liver disease (MASLD) has gained recognition, but the diagnostic accuracy of non-invasive markers in this context remains underexplored. This study aimed to evaluate the utility of the FIB-4 index for fibrosis prediction in CHB patients and investigate its performance in the distinct subgroup of CHB-MASLD.

Method: A prospective study from 2021 to 2022 included 109 CHB and 64 CHB-MASLD patients. All underwent liver stiffness measurement via ShearWave Elastography (SWE) and FIB-4 calculation. MASLD criteria were defined, creating CHB-alone and CHB-MASLD groups. Statistical analyses included t-tests, ROC curves, and correlation assessments.

Results: No significant age, gender, or ethnicity differences were observed between CHB and CHB-MASLD groups. CHB-MASLD patients exhibited higher BMI, increased prevalence of obesity, dysglycemia, and dyslipidemia. HBeAg negativity and nucleoside/tide treatment rates were comparable. FIB-4 and APRI scores were elevated in CHB-MASLD. ROC analysis revealed an AUC of 0.86 for FIB-4 in CHB, with an optimal cutoff of 1.95. Subgroup analysis by BMI showed consistent FIB-4 performance. In CHB-MASLD, the ROC curve showed an AUC of 0.61 (p = 0.12) indicating non-significance.

Conclusion: Our study affirms FIB-4’s robust performance in predicting fibrosis for CHB patients across varied BMI profiles. Yet, challenges surface when applying FIB-4 to those with concurrent CHB and MASLD. These limitations stress the urgency for refined fibrosis prediction tools, essential for navigating the complex interplay of viral and metabolic factors in the CHB-MASLD population.

FRI-438

Real-world clinical data-driven modelling on the initiation time of peripartum antiviral prophylaxis among pregnant women with chronic hepatitis B virus infection

Naijuan Yao¹, Shihao He², Jing Wang¹, Wenting Zhong¹, Mingwang Shen², Tianyan Chen¹. ¹Department of Infectious Disease, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, Shaanxi, China; ²China-Australia Joint Research Center for Infectious Diseases, School of Public Health, Xi’an Jiaotong University Health Science Center, Xi’an, Shaanxi, China
Email: chentianyan@xjtu.edu.cn

Background and aims: Recommendations for when to initiate antiviral prophylaxis for pregnant women with chronic hepatitis B virus (HBV) infection vary in the guidelines. We aim to explore the timing of antiviral prophylaxis for interrupting mother-to-child transmission (MTCT) of HBV in pregnant women with high viral loads using a mathematical model.

Method: We collected the real-world clinical data of 328 treated pregnant women with chronic HBV infection from July 2010 to December 2020 in the First Affiliated Hospital of Xi’an Jiaotong University. We developed a mathematical model to describe the viral kinetics of how HBV DNA levels decrease after antiviral prophylaxis. We calculated how long it would take exactly to decrease maternal viral load below a threshold of 5.3 log₁₀ IU/ml, at which the MTCT risk was negligible (0.04%), to avoid the usually overestimated time needed due to less frequent DNA testing. We derived the prophylaxis initiation time by using the childbirth gestational week of each woman to subtract the above time needed to reach the threshold value. We performed a sensitivity analysis to explore how a lower threshold of 4.0 log₁₀ IU/ml (corresponding to a 0.0% risk of MTCT) would affect the results.

POSTER PRESENTATIONS

Results: The median time for all 328 pregnant women with chronic HBV infection to reduce HBV DNA levels below the threshold of $5.3 \log_{10}$ IU/ml was 4.16 (range: 0.18–12.81) weeks, and it should be initiated to prophylaxis no later than 35.14 (range: 25.19–41.42) weeks. Particularly, prophylaxis initiation time should be no later than 33.93 (range: 25.19–39.45), 35.51 (range: 28.59–39.80), and 36.16 (range: 28.25–41.42) weeks for those women with viral loads $>8.0 \log_{10}$ IU/ml, >7.0 to $\leq 8.0 \log_{10}$ IU/ml, and >5.3 to $\leq 7.0 \log_{10}$ IU/ml, respectively. If the threshold value decreased to $4.0 \log_{10}$ IU/ml, the prophylaxis initiation time should be no later than 33.16 (range: 21.69–39.25) gestational weeks.

Conclusion: It is recommended that pregnant women with high HBV DNA level $>8.0 \log_{10}$ IU/ml should initiate antiviral prophylaxis no later than 25.19 gestational weeks to ensure enough safety. To further prevent MTCT of HBV infection and avoid immunoprophylaxis failures for these women, antiviral prophylaxis should be initiated no later than 21.69 gestational weeks.

FRI-439

An online web-based calculator accurately diagnoses immune tolerant phase in chronic HBV-infected patients

Chi Zhang¹, Yi-Qi Liu¹, Hong Zhao¹, Gui-Qiang Wang¹. ¹Peking University First Hospital, Beijing, China
Email: zhangcdoctor@126.com

Background and aims: There were different antiviral treatment strategies and prognoses between immune tolerant (IT) and non-IT in chronic hepatitis B (CHB) patients. However, existing non-invasive diagnostics were not precision. We aimed to explore new non-invasive models for diagnosing IT and assessed the risk of hepatocellular carcinoma (HCC) in IT patients.

Method: We included treatment-naïve CHB patients with liver biopsy who serological met the diagnostic criteria of IT (HBeAg-positive, HBV DNA >5 IgIU/ml, normal ALT). This study included four parts: in step 1, we described the clinical characteristics of IT patients. In step 2, we evaluated the value of non-invasive markers recommended by the guidelines for the diagnosis of IT. In step 3, a new model for the diagnosis of IT with non-invasive markers were developed and validated. In step 4, to assess the risk of developing HCC using 15 HCC prediction models for IT and non-IT.

Results: According to the criteria for the diagnosis of IT by WHO 2015 guidelines, 196 patients were finally included in this study, of which 83 were liver biopsy-proven IT. In the IT group age, qAnti-HBc, ALT, AST and LSM were lower. While, HBV DNA and HBSAg were higher. The risk of non-IT increased 1.2-fold and 3.92-fold in patients aged 30–40 (95%CI 1.00–4.81, $P = 0.049$) and >40 years (95%CI 2.28–10.60, $P < 0.001$), respectively, compared to those aged <30 years. Compared to HBV DNA >8 Ig IU/ml, the risk of non-IT was increased 4.33-fold and 9.96-fold in patients 7–8 Ig IU/ml ($p = 0.001$) and <8 Ig IU/ml ($p < 0.001$), respectively. The accuracy of non-invasive marker combinations for the diagnosis of IT did not exceed 0.800, whether in accordance with EASL2017/APASL2015, AASLD2018 or CHINA2019 criteria (0.709, 0.658 and 0.765, respectively). Using univariate analysis, LASSO regression and multivariate analysis, we created a CALA model (qAnti-HBc, LSM, AST, ALP) to diagnosing IT. The AUROC of CALA model reached 0.890 and 0.892 in training and validation sets, respectively, which were significantly higher than APRI, FIB-4 and LSM. For clinical convenience, we have made CALA model in an online web-based calculator and QR code. We included 15 hepatitis B related HCC prediction models (REACH-B, mREACH-BI, mREACH-BII, GAG-HCC, CU-HCC, LSM-HCC, PAGE-B, mPAGE-B, NGM1-HCC, NGM2-HCC, CAMD, RWS-HCC, AASL-HCC, REAL-B, aMAP) by searching the PubMed database. The risk of HCC was significantly lower in biopsy-proven IT than in biopsy-proven non-IT population (all $P < 0.01$). Subsequently, the CALA model was used to differentiate IT and the same results were obtained as those confirmed by liver biopsy (all $P < 0.01$, except CU-HCC model $P = 0.066$).

Conclusion: Online web-based calculator of CALA model can accurately and conveniently diagnose IT. Patients with liver biopsy or CALA model-proven IT were at a lower risk of developing HCC.

FRI-440

HBV precore and basal core promoter mutations exert direct cytopathic effect in humanized mice

Fengmin Lu¹, Guixin Li², Danli Yang¹, Hongsong Chen². ¹Department of Microbiology and Infectious Disease Center, School of Basic Medical Sciences, Peking University, Beijing, China, Beijing, China; ²Peking University People's Hospital, Peking University Hepatology Institute, Beijing Key Laboratory of Hepatitis C and Immunotherapy for Liver Disease, Beijing International Cooperation Base for Science and Technology on NAFLD Diagnosis, Beijing, China, Beijing, China
Email: lu.fengmin@hsc.pku.edu.cn

Background and aims: Basal core promoter (BCP, A1762T/G1764A) and precore (PC, G1896A) combined mutations occur increasingly with age in chronic HBV-infected patients. The association of the combined mutations and disease progression remains ambiguous. This study aimed to explore the effects of BCP+PC combined mutations on pathogenicity.

Method: Human hepatocyte chimeric mice were infected HBV by tail-vein injection with wild-type or BCP + PC mutant viral suspension. Liver samples of mice were collected at pre-designed point. Paraffin liver sections were used either for Hematoxylin and eosin (HandE) or immunohistochemistry (IHC) staining techniques. Total RNA of the liver tissues was extracted and RNA sequencing or RT-qPCR was conducted.

Results: HandE staining revealed that infection with HBV harboring BCP + PC mutations induced more extensive and severe degeneration of hepatocytes, as well as cytoplasmic vacuolation, paralleled with enhanced accumulation of core proteins. However, no significant change of intrahepatic HBSAg was observed in BCP + PC group. Next, transcriptomic analysis was carried out using RNA-Seq to differentiate the molecular characteristics in livers infected with WT and BCP + PC mutant strains. Gene set enrichment analyses implied that BCP + PC mutants might exacerbate hepatocyte injury by inducing endoplasmic reticulum (ER) stress, unfolded protein response, and activating tumor necrosis factor pathway. We also found that the intrahepatic mRNA level of glucose-regulated protein 78, XBP1, activating transcription factor 4, C/EBP-homologous protein, growth arrest and DNA damage 34, ER sulfhydryl oxidase 1 were potently increased in chimeric mice infected with BCP + PC mutants, suggesting the enhanced ER stress and reactive oxygen species production. Moreover, IHC staining of 8-hydroxyguanine (8-OHdG), a marker of oxidative DNA damage, demonstrated the presence of 8-OHdG-positive cells in BCP + PC groups, whereas few were detected in the WT group.

Conclusion: BCP and PC combined mutations might induce severe hepatocyte damage via aberrant core protein expression in human hepatocyte chimeric mice.

FRI-441

Metabolic dysfunction-associated steatotic liver disease (MASLD) evaluation in HBeAg negative chronic hepatitis B patients: italian cross-sectional observational study

Livio Crisculo¹, Riccardo Nevola², Alfredo Caturano³, Rosa Cotugno⁴, Martina Di Capua³, Raffaele Galiero³, Marco La Montagna³, Luca Rinaldi⁵, Ernesto Claar⁶, Ferdinando Carlo Sasso³, Grazia Anna Niro⁷, Aldo Marrone³. ¹Ospedali Riuniti Area Stabiese, Internal Medicine and Hepatology Unit, Castellammare di Stabia-Gragnano, Italy; ²AORN San Giuseppe Moscati, Department of Internal Medicine, Avellino, Italy; ³University of Campania Luigi Vanvitelli, Department of Advanced Medical and Surgical Sciences, Naples, Italy; ⁴IRCCS "Casa Sollievo della Sofferenza," Liver Unit, San Giovanni Rotondo, Italy; ⁵University of Molise, Department of Medicine and

Health Sciences, Campobasso, Italy; ⁶Ospedale Evangelico Betania, Liver Unit, Naples, Italy; ⁷IRCCS Casa Sollievo della Sofferenza, Gastroenterology Unit, San Giovanni Rotondo, Italy
Email: aldo.marrone@unicampania.it

Background and aims: Concomitant occurrence of HBV infection and metabolic dysfunction-associated steatotic liver disease (MASLD) has increased worldwide. Patients with chronic hepatitis B (CHB) and MASLD potentially have different pathophysiological conditions than those with MASLD alone. Experimental data suggest that MASLD may inhibit viral replication; conversely, the virus may exert effects on glycid and lipid metabolism. We aimed to evaluate the prevalence of MASLD in patients with CHB and analyze the associated factors.

Method: We conducted a cross-sectional observational study on HBeAg negative CHB Italian patients, enrolled in 2021–2023. The exclusion criteria were HCV and HDV coinfections, significant alcohol consumption, history or active hepatocellular carcinoma, decompensated cirrhosis, contraindications to transient elastography. Demographic, anthropometric, metabolic, laboratory and virological parameters were evaluated in the population. Liver fibrosis was evaluated non-invasively by FibroScan[®] and Fibrosis-4 Index, while SLD was assessed by ultrasonography and controlled attenuation parameter (CAP). Population was divided into two groups setting a threshold at CAP ≥ 248 dB/m to define hepatic steatosis. Logistic regression model was used to identify determinants associated with MASLD. Regression analysis of steatosis based on CAP score and quantitative HBV DNA was performed in HBeAg negative chronic infection subgroup, using Pearson's method.

Results: Study included 149 patients: 58.4% males, with an average age of 57.5 ± 12.3 years; 102/149 (68%) receiving antiviral therapy, among these 48% entecavir and 52% tenofovir. MASLD was observed in 48.3%; impaired fasting blood glucose or diabetes were present in 38.9%. Univariable analysis demonstrated a positive association of several metabolic parameters with MASLD (triglycerides, metabolic syndrome, fasting blood glucose, diabetes, obesity, body mass index-BMI), while inverse relationship between female sex, cirrhosis, HBeAg negative chronic infection and MASLD was revealed. At multivariable logistic regression analysis female gender was linked to a diminished likelihood of MASLD (OR: 0.14; 95% CI: 0.05–0.40; $p = 0.0003$), while both higher BMI (OR 1.41; 95% CI: 1.21–1.65; $p < 0.0001$) and diabetes (OR 6.81, 95% CI: 1.28–36.1, $p = 0.024$) was correlated with an elevated likelihood of MASLD. Regression analysis didn't show a statistically significant correlation between CAP score and HBV-DNA in HBeAg negative chronic infection subgroup ($r = -0.23$; $p = 0.13$).

Conclusion: The prevalence of MASLD by CAP evaluation in patients with CHB observed in our study was similar to that reported by previous studies. Diabetes and BMI represent the only metabolic factors associated with MASLD. MASLD in CHB patients is influenced more by obesity, insulin resistance and female sex hormones than by viral features.

FRI-442

Disease progression and persistent alanine aminotransferase elevation in HCV/HIV persons after DAA-related eradication: role of HBV and HDV co-infections

Roberto Rossotti¹, Alessandro Tavelli², Vincenzo Malagnino³, Valentina Svicher⁴, Eugenia Quiros-Roldan⁵, Alessandra Bandera⁶, Francesco Maria Fusco⁷, Marco Rivano Capparuccia⁸, Giovanni Battista Gaeta⁹, Valentina Mazzotta¹⁰, Massimo Puoti^{11,12}, Antonella D'Arminio Monforte². ¹ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; ²ICONA Foundation, Milan, Italy; ³Department of Medicine of Systems, University of Rome Tor Vergata, Rome, Italy; ⁴Department of Experimental Medicine, University of Rome Tor Vergata, Rome, Italy; ⁵University of Brescia and ASST Spedali Civili di Brescia, Department of Infectious and Tropical Diseases, Brescia, Italy; ⁶Infectious Disease Unit, Department of Internal Medicine, Fondazione IRCCS Ca, Granda, Ospedale Maggiore Policlinico, Department of Pathophysiology

Vanvitelli, Infectious Diseases Unit, Naples, Italy; ¹⁰Clinical Infectious Diseases Department, National Institute for Infectious Diseases Lazzaro Spallanzani IRCCS, Rome, Italy; ¹¹Infectious Diseases Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, Italy; ¹²School of Medicine and Surgery, University of Milan-Bicocca, Milan, Italy
Email: roberto.rossotti@ospedaleniguarda.it

Background and aims: Direct-acting antivirals (DAA) allow to achieve sustained virological response (SVR) also in HIV and especially HBV co-infection, whose replication is generally suppressed by HCV with consequent risks of HBV reactivation after eradication. Few data are available about triple/quadruple HIV/HCV/HBV \pm HDV co-infected individuals (3/4CoInf-i) with SVR. Aim of this study is to compare ALT normalization and severe liver-related events in HIV/HCV co-infected vs. HIV/HCV with occult B infection (OBI) vs. 3/4CoInf-i after HCV eradication.

Method: Study population: all HIV/HCV co-infected individuals with available HBV serology enrolled in ICONA/HepalCONA cohorts who achieved SVR after DAAs. Standard survival analysis was used to estimate ALT normalization (i.e., two consecutive values below 42 for men and 30 U/L for females) and two composite clinical outcomes: the first included liver-related events (hepatocellular carcinoma, hepatic decompensation, transplantation, death) in individuals with and without cirrhosis (CO1); the second evaluated only non-cirrhotics who developed a FIB4 increase >3.25 in addition to CO1 (CO2). Univariate/multivariable Cox regression analyses were performed to assess variables associated to these outcomes.

Results: The analysis included 1,182 individuals: 476 HIV/HCV, 650 HIV/HCV + OBI, 56 3/4CoInf-i (HDV serology was available for 33 subjects with 15 positivity). The 3/4CoInf-i had significantly higher proportion of cirrhotics (38.3%) and lower CD4 count (589 cell/mm³, IQR 409–867) and all received ART regimens with anti-HBV activity. This group was associated with lower likelihood to normalize ALT (aHR 0.67, 95%CI 0.47–0.97, $p = 0.035$) but, when HDV co-infection was included in the model, only the quadruple infection retained significance (aHR 0.20, 95%CI 0.05–0.82, $p = 0.025$).

We observed 54 events for CO1 and 104 for CO2. The adjusted models found that age and male sex were positively associated to both CO1 and CO2, while CD4 count was protective for the two outcomes. The 3/4CoInf-i group was not associated with CO1 or CO2.

Conclusion: Age, male sex and CD4 have an impact on disease progression greater than the presence of triple or quadruple infection under active anti-HBV regimens. The 3/4CoInf-i group achieves normal ALT values less commonly after SVR, but this outcome is mediated by HDV. A wide antiviral combination is essential to maintain liver function.

FRI-443

Compassionate use of REP 2165-Mg in chronic HBV/HDV patients with progressive liver disease and failure to previous pegIFN therapy

Gheorghe Placinta¹, Victor Pantea¹, Lilia Cojuhari¹, Valentin Ceboatarescu¹, Michel Bazinet², Andrew Vaillant². ¹Nicolae Testemitanu State University of Medicine and Pharmacy, Chişinău, Moldova; ²Replicor Inc., Montreal, Canada
Email: avallant@replicor.com

Background and aims: REP 2165 is an analog of REP 2139 no longer in development with identical activity to REP 2139 in HBV and HDV in clinical studies (achieving HBV functional cure and HDV cure) but with weaker liver accumulation. REP 2165-Mg drug product from the REP 401 study is being deployed to meet international demand for compassionate access to NAP therapy.

POSTER PRESENTATIONS

Method: Prior to REP 2165-Mg treatment, two chronic HBV/HDV Caucasian patients (1: female 46 y.o. and 2: male 51 y.o.) with rapid progression of liver disease (F3 fibrosis) received therapy with TDF + pegIFN. Patient 1 completed 48 weeks of pegIFN with HDV RNA TND (no HBsAg response) with HDV rebound after removal of pegIFN. After 50 weeks of pegIFN, patient 2 had only achieved a 1 log decline in HDV RNA (no HBsAg response). Existing TDF therapy in both patients was supplemented with weekly IV infusion of 500 mg REP 2165-Mg and 180 µg of pegIFN (pegIFN was uninterrupted in patient 2) scheduled for 48 weeks. Safety and biochemical response were monitored weekly and virologic response every 4 weeks using standard assays for quantitative HBsAg (LLOQ 0.05 IU/ml) and anti-HBs (cutoff for seroconversion 10 mIU/ml), HBV DNA (LLOQ 10 IU/ml) and HDV RNA (LLOQ 10 IU/ml).

Results: Patients 1 and 2 have completed 28 and 30 weeks of combination therapy. IV infusion of REP 2165-Mg in both patients was accompanied by fever and chills requiring supportive therapy for the first 4 weeks. REP 2165-Mg dosing was reduced to 250 mg QW after week 12 due to rapid elimination of HDV RNA. Administration since week 4 was asymptomatic with no supportive therapy and no other AEs have been observed. Patient 1 has experienced three discrete ALT flares during therapy (3× baseline) and patient 2 experienced ALT elevation starting at week persisting at 3× baseline from week 12 onward. ALT flares were otherwise asymptomatic with no changes in liver synthetic function. Patient 1 achieved HDV RNA loss persistent since week 12. HBsAg has declined 1.79 log from baseline (currently 136 IU/ml). Anti-HBs seroconversion has persisted since week 16 (currently 130 mIU/ml). Patient 2 achieved HDV RNA loss persistent since week 8. HBsAg has declined 4.5 log from baseline (currently 0.14 IU/ml). Anti-HBs seroconversion has persisted prior to week 12 (currently 130 mIU/ml).

Conclusion: Although REP 2165-Mg is no longer in clinical development, it demonstrates excellent safety and efficacy against HBV and HDV infection in patients with advanced liver disease with prior pegIFN failure. These results confirm previous clinical data, expand the database of NAP compassionate use and inform on the design of upcoming phase IIA studies.

Background and aims: The complexity of the Hepatitis B Virus (HBV) genetic makeup shows variations across different geographical regions, and specific HBV genotypes are associated with distinct clinical implications and treatment responses. While previous studies have identified predominant genotypes, there is a notable lack of a comprehensive geospatial evaluation of hepatitis B genotypes in Indonesia. This emphasizes the need for thorough investigations into

the prevalence of hepatitis B categorized by genotype in different regions.

Method: In our study, we utilized a geospatial approach to analyze the regional molecular epidemiology of HBV genotypes in addition to the determination of HBV subtypes and phylogenetic analysis of genotypes. Two hundred and seventy-eight HBV isolates and their clinical data were obtained from chronic hepatitis B patients located in two distant regions, DKI Jakarta and South Sulawesi, representing western and eastern parts of Indonesia, respectively. HBV surface antigen subtypes (*adw*, *adr*, *ayw*, or *ayr*) were determined using deduced amino acid sequences 122 and 160 in the 'a' determinant region. HBV genotype was determined from DNA sequences of the S gene of HBV DNA subjected to phylogenetic analysis using standard reference sequences. Patients' data were characterized according to demographics, genotype likelihood phylogeny, and geospatial hotspot analysis using Getis-Ord G_i^* statistics.

Results: Demographic data showed in Jakarta, the predominant HBV subtypes were 73.7% *adw*, 24.2% *adr*, and 2.1% *ayw*, with no detection of *ayr*. In South Sulawesi, the subtype distribution is more balanced, with 42.9% *adr*, 32.1% *adw*, 21.4% *ayw*, and a minor presence of 3.6% *ayr*. HBV isolates from DKI Jakarta were dominated by genotype B while South Sulawesi was genotype C ($p < 0.0001$). Geospatial analysis uncovered a higher prevalence of genotype C in the northern area of DKI Jakarta, contrasting with a more evenly spread occurrence of genotype B. Meanwhile, the distribution of HBV genotypes B and C in South Sulawesi was largely distributed across the region. Among these two regions, North Jakarta and Makassar appeared as significant hotspot cities for both genotype B and genotype C.

Conclusion: This early study indicates the distinct pattern in hepatitis B molecular epidemiology, emphasizing the necessity for a thorough study of the geospatial distribution of HBV genotypes in Indonesia.

Efficacy and safety of tenofovir alafenamide fumarate in preventing HBV vertical transmission in high maternal viral load: a multi-centre, prospective cohort study

Xingfei Pan¹, Fang He², Xujing Liang³, Jiangxia Qin⁴, Yanqiu Li⁵, Xueting Ou¹, Zicong Liang¹, Panpan Zhai¹, Liyang Zhou¹, Xiaoping Tang⁶. ¹The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; ²The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; ³The First Affiliated Hospital of Jinan University, Guangzhou, China; ⁴Huadu Maternal and Child Health Hospital of Guangzhou, Guangzhou, China; ⁵Panyu Maternal and Child Care Service Centre of Guangzhou, Guangzhou, China; ⁶Guangzhou Eighth People's Hospital, Guangzhou Medical University, Guangzhou, China
Email: panxf0125@163.com

Background and aims: Prevention of mother-to-child transmission (MTCT) is a key intervention to reduce the prevalence and burden of HBV. Few efficacy and safety data are published regarding tenofovir alafenamide fumarate (TAF) administered during pregnancy. We designed a multi-centre, prospective cohort study to evaluate efficacy and safety of TAF in pregnant women with chronic HBV infection during mid to late pregnancy.

Method: We enrolled pregnant women with HBV DNA levels >200 000 IU/ml. They were randomized to receive TAF or tenofovir disoproxil fumarate (TDF) from 24–35 weeks of gestation until

delivery. All infants received HBV immune prophylaxis as planned. Primary end points were maternal HBV DNA reduction at delivery and infant's hepatitis B surface antigen (HBsAg) positivity at 7 months. Secondary end points were rates of adverse events and defects in infants.

Results: From 1 June 2021 to 31 January 2023, 168 mothers were enrolled from the Third Affiliated Hospital of Guangzhou Medical University, the First Affiliated Hospital of Jinan University, Huadu Maternal and Child Health Hospital of Guangzhou, and Panyu Maternal and Child Care Service Centre of Guangzhou. Baseline characteristics were comparable between 2 groups. In TAF group, 88 mothers were enrolled and 94 infants were born (six pairs of twins). Mean maternal age, gestational age, alanine aminotransferase (ALT) level and HBV DNA load at baseline were 30.2 ± 4.3 years, 28.6 ± 2.4 weeks, 22.4 ± 15.6 U/L and 7.0 ± 1.1 log₁₀ IU/ml, respectively. Twenty (22.7%) cases were of in vitro fertilization, 20 (22.7%) cases had anemia, and 5 cases (5.7%) had gestational diabetes. In TDF group, 80 mothers were enrolled and 83 infants were born (one set of triplets and one pair of twins). Mean maternal age, gestational age, ALT level and HBV DNA load were 30.5 ± 4.4 years, 28.3 ± 2.3 weeks, 31.3 ± 47.6 U/L and 7.1 ± 1.0 log₁₀ IU/ml, respectively. Eleven (13.8%) cases were of in vitro fertilization, 18 (22.5%) cases had anemia, and 4 (5%) cases had gestational diabetes. The median duration of treatment was 10 (1–16) and 11 (3–15) weeks in TAF and TDF groups, respectively. The serum HBV DNA load was reduced by 3.5 ± 1.1 and 3.6 ± 1.2 log₁₀ IU/ml at delivery in TAF and TDF groups with no statistical difference between groups ($p = 0.644$). None of infants were HBsAg positive at 7 months of age. Neither mothers nor infants experienced any serious adverse events during following-up. Seventeen (19.3%) maternal complications (mainly preterm labor and premature rupture of membranes) in TAF group and 12 (15%) in TDF's ($p = 0.460$). Five (5.3%) TAF and 5 (6.0%) TDF cases had fetal intrauterine distress ($p = 0.839$). None of the babies had any congenital defects. There was 1 case of delayed fetal growth and development in both groups and 1 case of slow fetal growth in TDF group during the follow-up.

Conclusion: TAF is as effective and safe as TDF in interrupting MTCT in both mothers and infants.

WED-391

Long-term virological and clinical outcomes of patients with HDV-related compensated cirrhosis treated with bulevirtide monotherapy for up to 120 weeks: a retrospective multicenter european study (save-d)

Background and aims: Bulevirtide (BLV) has been approved for treatment of chronic hepatitis D virus (HDV) infection in Europe in 2020, however, long-term real-life effectiveness and safety data in large cohorts of HDV patients with cirrhosis treated beyond week 48 are lacking.

Method: Consecutive HDV patients with compensated cirrhosis starting BLV 2 mg/day sc since September 2019 were included in a retrospective multicenter real-life European study (SAVE-D). Clinical, biochemical, virological features and liver-related events were collected. Virological (HDV-RNA undetectable or ≥ 2 -log decline vs. baseline), biochemical (ALT < 40 U/L), combined response (biochemical + virological) and adverse events were assessed. HDV-RNA was quantified locally.

Results: 243 patients receiving BLV monotherapy up to 120 weeks [median follow-up: 72 (range 24–120) weeks] were included: age 49 (IQR 39–58) years, 60% men, ALT 80 (55–130) U/L, liver stiffness measurement (LSM) 18.2 (13.0–26.2) kPa, platelets 94 (68–146) G/L, 100% CPT score A, 52% with varices, 10% HIV-positive, 11% with a history of ascites, 6% with active HCC, 92% on NUC. Baseline HDV-RNA and HBsAg levels were 5.3 (3.4–4.1) log IU/ml and 3.8 (4.1–6.5) log IU/ml, respectively. Virological responses at W24, W48, W72, W96, W120 were 52%, 66%, 70%, 77% and 90%, respectively, while HDV RNA undetectability was achieved by 18%, 31%, 42%, 47%, and 52% of patients. Biochemical and combined responses were 53%, 62%, 63%, 65%, 71%, and 33%, 45%, 50%, 51% and 67%, respectively. Patients with < 1 log HDV-RNA decline vs. baseline declined from 23% at W24 to 7% at W96. Responses were similar in HIV positive and negative patients. AST, GGT, albumin, IgG and LSM values significantly improved throughout treatment (LSM baseline 18.2 kPa \diamond 10.0 kPa W120). Lower baseline HDV-RNA was the only predictor of HDV-RNA undetectability at week 48 (HR 0.75; 95% CI 0.60–0.94, $p = 0.01$). Bile acids significantly increased, 8% patients reported mild and transient pruritus, 3% injection site reactions. Overall, 19 (8%) patients discontinued treatment for the following reasons: grade 3 maculopapular rash ($n = 1$), non-compliance ($n = 1$), long-term HDV-RNA undetectability ($n = 2$), virological non-response ($n = 3$), lost to follow-up ($n = 7$); in additional 5 patients, add-on PegIFN to BLV monotherapy was performed. The W120 cumulative incidence of de-novo HCC and decompensation was 4.2% (95% CI 2–7%) and 3.4% (95% CI 1–6%), respectively. 11 patients underwent liver transplantation (HCC $n = 9$; decompensation $n = 2$) and 4 died of BLV-unrelated causes (sepsis, pneumonia, HCC, intestinal infarction).

Conclusion: BLV 2 mg/day monotherapy up to 120 weeks was safe and effective in patients with HDV-related compensated cirrhosis. Virological and clinical responses continued to increase during long-term BLV therapy. Liver-related complications were rare.

WED-392

Improvement in liver histology is observed in most patients with chronic hepatitis delta after 48 weeks of bulevirtide monotherapy

Email: ben.da@gilead.com

Background and aims: Patients with chronic HDV (CHD) treated with bulevirtide (BLV) in the Phase 3 study MYR301 showed superior responses at week (W) 48 vs controls based on the combined response end point of virologic response (VR; ≥ 2 log₁₀ IU/ml decline from baseline [BL] or undetectable HDV RNA) and ALT normalization. Recent sub analyses has shown that ALT improvement often occurs discordant of VR with BLV. We now explore the relationship between virologic, biochemical, and histologic change through 48W in MYR301.

Method: In MYR301, patients were randomized 1:1:1 to 144W of BLV 2 mg or 10 mg or control (48W no BLV followed by 96W of BLV 10 mg), with an additional 96W of follow-up after the end of treatment. Liver biopsy was performed per study protocol at BL and W48 in the absence of contraindications. This analysis focused on the patients with paired biopsies. Viral response categories at W48 included VR, partial response (PR; ≥ 1 but < 2 log₁₀ IU/ml) or non-response (NR; < 1 log₁₀ IU/ml). Histologic parameters included histologic activity index (HAI; 0–18), HAI category (0–4), and Ishak fibrosis score (0–6). Improvement in HAI or fibrosis was defined as ≥ 1 point. Histological improvement was defined as ≥ 2 point improvement in HAI with no worsening of fibrosis. The evolution and correlation of laboratory, virologic, and histologic parameters across groups was examined.

Results: Of the 150 randomized patients, 83 (55%) had paired biopsy data: 25-BLV 2 mg, 31-BLV 10 mg, and 27-control. At BL ($n = 83$), mean age 42 years, 52% males, 84% White, 33% with compensated cirrhosis and 61% were on concomitant nucleos(t)ide analogue therapy. Mean HDV RNA and median ALT, HAI, and Ishak fibrosis score was 5.1 log₁₀ IU/ml, 92 U/L, 9, and 2. At W48, 80% (45/56), 11% (6/56), and 9% (5/56) of patients treated with BLV achieved VR, PR, and NR while no control achieved VR. Similar median change in ALT U/L was observed across viral response groups: VR, –51; PR, –56; NR, –64; which was superior compared to control, –11. ALT normalization occurred in most with VR (69%, 31/45) and PR (67%, 4/6) but also occurred in 1 with NR (20%, 1/5) and 2 control (7%, 2/27). Decrease in ALT was observed in 89% (50/56) of BLV treated patients (including all patients with PR ($n = 6$) and NR ($n = 5$)); of those with ALT decrease, 80% (40/50) also had HAI improvement. A higher likelihood of improvement in HAI category and a greater decrease in median HAI from BL was observed with VR: 69% (31/45), –4 and PR: 83% (5/6), –3 compared to NR: 20% (1/5), 0 and control: 30% (8/27), –1. ALT normalization did not have a clear correlation with the degree of HAI improvement. Improvement in fibrosis occurred in VR: 58% (26/45), PR: 33% (2/6), NR: 25% (1/4), and control: 30% (8/27). Histological improvement occurred in VR: 69% (31/45), PR: 83% (5/6); NR: 25% (1/4); and control: 33% (9/27).

Conclusion: Improvement in liver histology is observed in most patients with CHD after 48 weeks of BLV monotherapy.

WED-393

Association between post-treatment ALT elevation and subsequent hepatitis B surface antigen seroclearance in chronic hepatitis B patients stopping nucleos (t)ide analogue therapy

Yao-Chun (Holden) Hsu¹, Ying-Nan Tsai², Jia-Ling Wu³, Cheng-Hao Tseng⁴, Yi-Ling Wu², Shang-Chen Tseng², Chih-Lung Hung², Jaw-Town Lin². ¹E-Da Hospital, Kaohsiung; ²E-Da Hospital, Kaohsiung, Taiwan; ³National Cheng Kung University, Tainan, Taiwan; ⁴E-Da Cancer Hospital, Kaohsiung
Email: holdenhhsu@gmail.com

Background and aims: Serum alanine aminotransferase (ALT) frequently rises after chronic hepatitis B (CHB) patients discontinue nucleos (t)ide analogue (NA). ALT elevation was presumed to be conducive of hepatitis B surface antigen (HBsAg) seroclearance but supporting or refuting evidence was lacking. We aimed to clarify the association between ALT elevation and HBsAg seroclearance following NA cessation.

Method: This is a retrospective, multi-center cohort study based on reviewing all CHB patients who had discontinued NA after being treated for one year or longer between April 01, 2004 and May 24, 2022. Patients with malignancy, hepatic insufficiency, viral coinfections, or organ transplantation were excluded. The primary outcome was the association between ALT flares, defined as ALT >5 times the upper limit of normal (ULN) and HBsAg seroclearance after NA cessation. The incidence of HBsAg seroclearance was estimated using the competing risk analysis to account for informative censoring by retreatment. Time-dependent sub-distribution hazard models were developed to clarify the association of ALT elevation with subsequent HBsAg seroclearance.

Results: A total of 850 patients were eligible (74.5% male, with a median age of 53.2 years). During a median post-treatment follow-up of 3.7 years (IQR, 1.4–6.3), HBsAg seroclearance occurred in 47 patients, at an average annual rate of 1.37% (95% confidence interval [CI], 1.01–1.83%) and a cumulative incidence of 13.2% (95% CI, 9.59–17.39%) at 10 years. Peak serum ALT level post-NA cessation was significantly lower in patients achieving HBsAg seroclearance (median, 77 U/L; IQR, 42–136) compared to those who did not achieve HBsAg seroclearance (median, 127 U/L; IQR, 47–341; $p < 0.0001$). Post-treatment ALT flare was associated with a lower incidence of HBsAg seroclearance (sub-distribution hazard ratio, 0.27; 95% CI, 0.12–0.63). The inverse association between ALT elevation and HBsAg seroclearance was consistently observed in the sensitivity tests with ALT threshold set at $2 \times$ ULN or $1 \times$ ULN. Among the subset of 399 patients with quantitative HBsAg data available at end of treatment (EOT), the association between elevated ALT and HBsAg seroclearance was no longer significant after adjusting for EOT HBsAg levels. In this subgroup analysis, a lower EOT HBsAg level was associated with a higher incidence of HBsAg seroclearance regardless of ALT elevation during the follow-up.

Conclusion: Following NA cessation, patients who experienced ALT elevation, whether the threshold was set at 5-, 2-, or 1-fold ULN, had a significantly lower incidence of subsequent HBsAg loss. No independent association between ALT elevation and HBsAg clearance was noted in the subgroup analyses adjusted for EOT qHBsAg. Our data refutes post-treatment ALT elevation may aid in clearing HBsAg and suggest NA cessation be avoided in patients at risk of ALT flares.

WED-394

Hepatic flares after nucleos (t)ide analogue cessation in HBeAg-negative hepatitis B: results from the Nuc-Stop study

Email: marte.holmberg@online.no

Background and aims: Hepatic flares are frequently reported after nucleos (t)ide analogue (NA) cessation and can be detrimental leading to liver injury, hepatic decompensation or even death. We aimed to describe flares and predictive factors for flares after NA cessation in a prospective trial.

Method: This was a sub-analysis of the Nuc-Stop Study, a prospective, randomized, multicenter trial where 127 HBeAg-negative patients, virally suppressed for at least 24 months, stopped NA treatment and were followed up for 36 months. Flares were defined as ALT increase above $2 \times$ upper limit of normal (ULN) and divided into three groups: mild (ALT $2\text{--}5 \times$ ULN), moderate (ALT $5\text{--}20 \times$ ULN), and severe (ALT $>20 \times$ ULN). The timing and severity of flares were described. Kruskal Wallis tests were used to compare groups. Logistic regression was used to identify predictors of flares.

Results: A flare was observed in 60 (47.2%) patients. The flare was mild in 28 (22.1%), moderate in 22 (17.3%), and severe in 10 (7.9%) patients. Of these, early flares within 3 months after NA cessation, were observed in 33 (55.0%) patients, whereas 8 (13.3%) had a flare between 3 and 6 months, 5 (8.3%) between 6 and 12 months, and 14 (23.3%) after 12 months. Most of the patients had been treated with tenofovir (97, 76.4%), the remaining with entecavir. The median time from treatment stop to first flare was significantly shorter for patients who stopped tenofovir (2.1 months, IQR 1.9–8.4) than for those who stopped entecavir (5.8, IQR 5.1–12.2) ($p = 0.01$). Genotype was known in 115 (90.6%) patients, 35 (27.6%) had genotype B or C and 80 (63.0%) had other genotypes (A, D, E). Median time in months from treatment stop to flare was 5.7 (IQR 2.0–12.2) for patients with genotype B or C and 2.8 (IQR 1.9–6.5) for patients with other genotypes. Median time to severe flares was 2.1 (IQR 1.8–3.0) months; all except one were observed within 6 months after NA cessation. All 10 patients with severe flares had been treated with tenofovir, the median peak ALT was 1403 (range 874–2600) U/L. Median peak HBV DNA was 20 300 000 (IQR 2 300 000–260 000 000) IU/ml, and most commonly occurred on the last visit before peak ALT. ALT declined to normal levels and HBV DNA was fully suppressed after restart of NA therapy. No patients developed decompensated liver disease. Age (per 1-year increment; adjusted odds ratio 1.07; 95% CI 1.02–1.12) and qHBsAg at the time of NA cessation (per 1 log₁₀ IU/ml increment; adjusted odds ratio 1.96; 95% CI 1.12–3.43) were independent predictors of flares.

Conclusion: Flares occurred in half of the patients after NA cessation and were associated with age and qHBsAg level. Severe flares were uncommon, primarily occurred within 6 months, and normalized quickly after restart of NA therapy.

Background and aims: Chronic hepatitis delta (CHD) infection is the most severe form of viral hepatitis. Bulevirtide (BLV), 2 mg, is approved for the treatment of compensated CHD in the European Union. Currently, the clinical relevance of target not detected (TND) versus below the lower limit of quantification (<LLOQ) for HDV RNA levels is unknown. The Phase 2b study MYR204 (NCT03852433) evaluated finite treatment with BLV with or without pegylated interferon alfa-2a (PegIFN) in patients with CHD. Here we compared the ability to maintain the post-treatment virologic response based on achieving undetectable (<LLOQ with TND) HDV RNA or <LLOQ with target detected (<LLOQ, TD) at end of treatment (EOT).

Method: Patients were randomised (N = 174; 1:2:2:2) and stratified based on the absence or presence of compensated cirrhosis to receive (A) PegIFN for 48 weeks (W), (B) BLV 2 mg + PegIFN, (C) BLV 10 mg + PegIFN for 48W followed by 48W of monotherapy with BLV 2 mg or 10 mg, respectively; or (D) BLV 10 mg for 96W. All patients were followed for up to 48W after EOT (FU-48). The primary end point was the proportion of patients who achieved undetectable HDV RNA at 24W post-EOT. HDV RNA levels were determined by RT-qPCR using RoboGene 2.0 (LLOQ 50 IU/ml, limit of detection 6 IU/ml). Virologic response rates at FU-48 were compared between patients with undetectable HDV RNA and those with HDV RNA <LLOQ, TD at EOT.

Results: Demographics and baseline characteristics were similar across groups: male (71%), White (87%), and mean (SD) age 41 (8.7) yrs. Overall, 34% had compensated cirrhosis, 48% received concomitant nucleos(t)ide analogue therapy, and 48% had prior interferon experience. Mean (SD) HDV RNA, alanine aminotransferase, and liver stiffness were 5.3 (1.2) log₁₀ IU/ml, 114 (95) U/L, and 13.1 (7.7) kPa, respectively. At EOT, 42% (73/174) achieved undetectable HDV RNA: A: 21% (5/24), B: 44% (22/50), C: 70% (35/50), and D: 22% (11/50). Additionally, 19% (33/174) were <LLOQ, TD: A: 4% (1/24), B: 18% (9/50), C: 16% (8/50), and D: 30% (15/50). Of the patients with undetectable HDV RNA at EOT, 60% (44/73) maintained undetectable HDV RNA at FU-48: A: 100% (5/5), B: 55% (12/22), C: 60% (21/35), and D: 55% (6/11). Moreover, 29% (21/73) had HDV RNA >LLOQ: B: 27% (6/22), C: 31% (11/35), and D: 36% (4/11). Four patients (5%; 4/73) became <LLOQ, TD, and 5% (4/73) discontinued early by FU-48. Of those who were <LLOQ, TD at EOT, only 6% (2/33) had undetectable HDV RNA (1 each

in groups B and C) and 9% (3/33) remained <LLOQ, TD at FU-48, while 73% (24/33) had HDV RNA >LLOQ: A: 100% (1/1), B: 56% (5/9), C: 63% (5/8), and D: 87% (13/15); 4 discontinued early.

Conclusion: In patients with compensated CHD, achieving on-treatment undetectable HDV RNA with TND is a predictor of undetectable HDV RNA in the post-treatment period. The majority of patients with HDV RNA <LLOQ, TD at EOT had virologic rebound at FU-48.

WED-396

Changes in metabolic parameters after switching from tenofovir disoproxil fumarate to tenofovir alafenamide among chronic hepatitis B patients: a randomized, open-label controlled trial

Titinan Veerachit-O-larn^{1,2}, Thanapat Atthakitmongkol³, Wanwarang Teerasamit⁴, Supot Nimanong³, Siwaporn Chainuvati³, Phunchai Charatcharoenwitthaya³, Tawesak Tanwandee³, Watcharasak Chotiyaputta³. ¹Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; ²Division of Gastroenterology, Department of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand; ³Division of Gastroenterology, Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; ⁴Division of Diagnostic Radiology, Department of Radiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand
Email: watcharagi@gmail.com

Background and aims: Tenofovir alafenamide (TAF) is increasingly preferred over Tenofovir disoproxil fumarate (TDF) due to its lower nephrotoxicity and bone loss. However, the current data have shown controversy regarding metabolic outcomes among patients treated with TAF compared to those treated with TDF. The aim of this study is to evaluate the effect of TAF and TDF on metabolic parameters in chronic hepatitis B (CHB) patients.

Method: A total of ninety CHB patients treated with TDF were enrolled and randomly assigned to either switch to TAF (TAF group, n = 46) or continue TDF (TDF group, n = 44). Metabolic profiles were assessed at baseline, 24-week, and 48-week intervals through biochemical laboratory tests. Carotid Doppler Ultrasonography was conducted by a single radiologist who was blinded to the study group, evaluating carotid intima-media thickness (CIMT) at baseline and at the end of the study. All patients received advice from the dietician nurse and underwent continuous diet monitoring for one year in order to avoid high lipid and high hyperglycemic diets. The primary outcome was the change in lipid profile from baseline.

Results: The mean age of the patients was 59.4 ± 8.2 years, with a male predominance of 63.0%, and the mean body mass index (BMI) was 23.5 ± 4.1 kg/m². The baseline characteristics including BMI, fasting blood sugar (FBS), glycated hemoglobin (HbA1c), total cholesterol (TC), triglyceride (TG), high-density lipoprotein (HDL), low-density lipoprotein (LDL), CIMT, and co-morbidities were similar between both groups. At the end of the study, there were significant changes between the TDF and TAF groups in TC (173.6 ± 34.9 and 196.9 ± 37.4 mg/dL, respectively, p = 0.003) and TG (83.2 ± 38.5 and 118.8 ± 78.3 mg/dL, respectively p = 0.007). Significant increases in TC and TG levels were observed in the TAF group compared to the TDF group after 48 weeks of follow-up (p = 0.024 and p = 0.033, respectively). After 48-week, the percentage changes in FBS and HbA1c were significantly greater in the TAF group [FBS; TAF 6.4 ± 10.5% vs TDF 0.6 ± 12.2% (p = 0.017) and HbA1c; TAF 2.1 ± 4.5% vs TDF - 0.03 ± 3.7% (p = 0.015)]. However, no significant differences in HDL and LDL were observed between the groups over 48 weeks. Regarding CIMT, both groups had a slight decrease in mean common carotid artery (CCA) thickness and maximum internal carotid artery (ICA) thickness from baseline [CCA thickness; TAF - 5.6 ± 7.3% vs TDF - 2.5 ± 25.1% (p = 0.416) and maximum ICA thickness; TAF - 7.1 ± 18.3% vs TDF - 9.6 ± 18.5% (p = 0.517)]; however, the differences between the two groups were not statistically significant.

Conclusion: Patients with CHB treated with TAF demonstrated a significant increase in metabolic parameters, including TC, TG, FBS, and HbA1c compared to those treated with TDF. However, no differences were observed in HDL, LDL, and CIMT over the 48 weeks of follow-up. (Trial registration number: TCTR20220209003).

Email: wrkim@stanford.edu

Background and aims: Chronic hepatitis B (CHB) is a leading cause of hepatocellular carcinoma (HCC). Antiviral therapy with nucleot (s)ide analogues (NAs) has been shown to reduce HCC risk. This pooled analysis of four phase 3 studies (GS-US-174-0102 [Study 102], GS-US-174-0103 [Study 103], GS-US-320-0108 [Study 108], and GS-US-320-0110 [Study 110]) aimed to assess impact of tenofovir (TFV)-based NAs on long term HCC risk in CHB patients, utilizing three validated risk prediction algorithms.

Method: Studies 102 and 103 randomized patients 2:1 to double-blind (DB) treatment with tenofovir disoproxil fumarate (TDF) or adefovir dipivoxil (ADV) for 48 weeks, then open-label (OL) TDF, whereas Studies 108 and 110 randomized patients 2:1 to DB treatment with tenofovir alafenamide (TAF) or TDF for up to 144 weeks, then OL TAF. All patients were assessed over 384 weeks (8 years). HCC risk was estimated using the following models: Risk Estimation for HCC in Chronic Hepatitis B (REACH-B); modified Platelet Age Gender-HBV (mPAGE-B); and age-Male-ALBI-Platelets (aMAP). Primary outcomes included: HCC incidence (via standardized incidence ratios [SIRs] of HCC based on ratio of observed vs. model-predicted cases [REACH-B]); and the proportions of patients who shifted from baseline risk categories (aMAP and mPAGE-B).

Results: In total, 1,939 (n = 641 from 102/103 and n = 1,298 from 108/110) patients were included in the pooled analysis. By Year 8, 41 (2.1%) patients had developed HCC. By multivariate analysis, older age, male sex, and cirrhosis at baseline were associated with HCC development. By REACH-B, the SIR was 0.39 (95% confidence interval: 0.29, 0.53; p < 0.0001), indicating the observed incidence to be 61% lower than the predicted incidence; for patients with cirrhosis, the SIR was 46% lower. By aMAP and mPAGE-B models, most patients were at low- or medium-risk for HCC development at baseline, and either stayed the same or shifted to a lower risk category at Year 8, while most high-risk patients had shifted to at least medium-risk by Year 8.

Conclusion: In this large dataset of prospectively followed CHB patients, HCC risk was significantly impacted with long-term TFV-based treatment in CHB patients with and without cirrhosis.

HBsAg loss in inactive chronic hepatitis B carriers is dependent on level of qHBsAg and interferon response: a randomised control trial

Seng Gee Lim¹, Guan Huei Lee², Yock Young Dan³, Yin Mei Lee⁴, Htet Htet Toe Wai Khine⁵, Yuh Ling Amy Tay⁶, Cindy Seah⁷, Liang Shen⁵, Edwin, Shih-Yen Chan⁸, Martin Hibberd⁹. ¹National University Health System, Yong Loo Lin School of Medicine, Singapore, Singapore; ²National University Health System, Singapore; ³National University Health System, Yong Loo Lin School of Medicine, Singapore, Singapore; ⁴National University Health System, Singapore, Singapore; ⁵Yong Loo Lin School of Medicine, Singapore, Singapore; ⁶Yong Loo Lin School of Medicine, Singapore, Singapore; ⁷National University Health System, Singapore, Singapore; ⁸Singapore Clinical Research Institute, Duke-NUS Medical School, Singapore, Singapore; ⁹London School of Hygiene and Tropical Medicine, London, United Kingdom
Email: mdclimsg@nus.edu.sg

Background and aims: Peginterferon therapy of Chronic Hepatitis B (CHB) carriers how mixed results for HBsAg loss, but its unclear whether low qHBsAg (<1000 IU/ml) or low HBV DNA (<2000 IU/ml) are more important.

Method: This was a 3-arm RCT of peginterferon alpha2a (PEG) (pegasys, Roche) 180mcg weekly randomised 1:1:1 to 24 weeks (PEG24), 48 weeks (PEG48) or no treatment (C) in CHB carriers (clinicaltrials.gov:NCT02992704). Patients were randomly assigned based on: HBsAg (+)>6months, HBeAg (-), normal ALT, HBV DNA ≤2 × 10⁴ IU/ml or qHBsAg≤1000 IU/ml; absence of cirrhosis, treatment naive, absence of HCV/HDV/HIV coinfection. The primary end point was HBsAg loss 24weeks after treatment, and study size of 90 patients had 80% power to detect a 25% difference between any PEG arm and control. Data analysis was performed using SPSSv20 based on ITT analysis. Baseline and on-treatment variables and multivariate analysis were used to predict HBsAg loss at end-of-treatment (EOT) and end of 24weeks followup (FU24). PAXgene transcriptome analysis was performed on relevant patients.

Results: Baseline characteristics were similar between groups. HBsAg loss occurred in a total of 7/30 (23.3%) in PEG48, 9/30 (30%) in PEG24 and 0/30 (0%) in C at the EOT (p = 0.007) but 5/30 (16.7%) in PEG48, 5/30 (16.7%) in PEG24 and 1/30 (3.4%) in C at FU24 (p = 0.093). Baseline predictors of HBsAg loss at FU24 showed qHBsAg and ALT were significant by logistic regression with backwards model selection (p = 0.002, and p = 0.04 respectively). ROC curve analysis showed AUROC 0.896 (95% CI 0.806–0.986), with threshold of qHBsAg <76 IU/ml, had 100% sensitivity and 62% specificity for HBsAg loss at FU24. There were three distinct patterns (clusters) of interferon response despite qHBsAg <76 IU/ml, based on their HBsAg reduction at week 12. Cluster 1 had a HBsAg reduction of 2.19logIU/ml, cluster 2 had a mean reduction of 1logIU/ml and cluster 3 had a mean reduction of 0.05logIU/ml. Responders (HBsAg loss) occurred in 2/2 in cluster 1, 7/13 in cluster 2 and 5/15 in cluster 3. We examined responders and non-responders using PAXgene transcriptome analysis and found that responders had 55 differentially expressed genes of which 37 were upregulated. The most significantly upregulated was MMP8 and a cluster of 13 genes which were enriched in the neutrophil degranulation pathway (p = 5.59 × 10⁻¹²). There were 282 adverse events mostly interferon related (90%). There were 4 Serious Adverse Events but no deaths.

Conclusion: HBsAg loss with PEG in inactive carriers leads to 16.7% HBsAg loss with low baseline qHBsAg and interferon responsiveness driving HBsAg loss but not HBV DNA. A novel neutrophil enriched pathway was found in responders based on transcriptome analysis.

The composition of HBsAg along with HDV-RNA predicts virological response in chronic hepatitis delta patients treated with bulevirtide for 48 weeks

Stefano D'Anna¹, Romina Salpini², Elisabetta Degasperis³, Leonardo Duca¹, Maria Paola Anolli³, Lorenzo Piermatteo², Dana Sambarino³, Marta Borghi³, Floriana Facchetti³, Francesca Ceccherini Silberstein¹, Riccardo Perbellini³, Pietro Lampertico^{3,4}, Valentina Svicher². ¹Department of Experimental Medicine, University of Rome "Tor Vergata", Rome, Italy; ²Department of Biology, University of Rome "Tor Vergata", Rome, Italy; ³Division of Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; ⁴CRC "A. M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy
Email: stefanodanna26@gmail.com

Background and aims: HDV exploits HBV surface protein (HBsAg) for releasing of progeny and entry into hepatocytes. HBsAg consists of 3 different forms: Large- (L-HBs), Middle- (M-HBs) and Small-HBsAg (S-HBs). L-HBs is predominantly present in virions and mediates binding to NTCP receptor, while the lack of M-HBs production is known to favour the release of replication-competent virions. Here, we investigate the kinetics of HBs forms under bulevirtide treatment (BLV).

Method: 28 consecutive patients with HDV-related compensated cirrhosis starting BLV 2 mg/day monotherapy were enrolled in this retrospective/longitudinal study, all under effective NUC treatment at entry. L-HBs, M-HBs and S-HBs were quantified by *ad-hoc* ELISAs in baseline and week 48 (W48) samples (Beacle). HDV RNA was quantified by Robogene 2.0. Virological response was defined as HDV RNA undetectable or >2log decline compared to baseline, biochemical response as ALT normalization.

Results: At baseline, median (IQR) age was 53 (40–63) years, liver stiffness 19.4 (15.4–32.9) kPa, ALT 106 (77–147) U/l, serum HDV RNA 5.4 (4.4–6.0) log IU/ml and HBsAg levels 3.7 (3.4–4.9) log IU/ml. Pre-treatment median (IQR) levels of S-HBs, M-HBs and L-HBs were 3999 (1482–7184), 1032 (305–2222) and 6 (2–14) ng/ml, respectively. At W48, serum HDV RNA declined by 3.1 (1.8–3.7) log IU/ml while virological and biochemical responses were observed in 71% and 75% of patients, respectively. A >10% decrease of S-HBs, M-HBs and L-HBs levels was observed in 57%, 54% and 39% of patients with a median (IQR) decline of 1095 (839–2403), 145 (39–350) and 10 (4–15) ng/ml, respectively. Baseline HDV RNA <5 log IU/ml was associated with HDV RNA <100 IU/ml at W48 (75% with vs 25% without, $P=0.02$). A similar correlation was observed for baseline L-HBs <9 ng/ml (62.5% with vs 25% without, $P=0.05$). The combination of pre-treatment L-HBs <9 ng/ml + HDV RNA <5 log IU/ml was the best predictor for achieving HDV RNA <100 IU/ml (PPV:87.5%, NPV:70%; $P=0.01$). This combination showed also the best diagnostic accuracy for predicting HDV RNA <100 IU/ml plus ALT normalization (PPV:75%, NPV:75%; $P=0.03$). A different scenario was observed for M-HBs. Patients with baseline M-HBs >500 ng/ml had a significantly greater virological response than those with baseline M-HBs <500 ng/ml (HDV RNA decline of 3.4 [2.5–3.8] vs 1.6 [1.2–3.2] log IU/ml, $P=0.03$). Baseline M-HBs >500 ng/ml predicted the achievement of virological response at W48 of BLV (PPV: 88.8%, NPV: 60%; $P=0.01$). Superimposable results were observed in a subgroup of 12 patients with serum HDV RNA <5 log IU/ml at baseline (PPV: 100%, NPV: 57%; $P=0.038$).

Conclusion: Quantification of L-HBs and M-HBs along with serum HDV RNA may reflect the burden of circulating infectious or replication-competent virions in the setting of HBV/HDV co-infection, possibly providing a new tool to identify patients more likely to respond to BLV monotherapy.

WED-402

Risk of hepatocellular carcinoma after curative treatment when switching from Tenofovir Disoproxil Fumarate or Entecavir to Tenofovir Alafenamide: a real-world multicenter cohort study

Hyunjae Shin¹, Yunmi Ko¹, Youngsu Park¹, Yoon Jun Kim¹. ¹Seoul National University Hospital, Seoul, Korea, Rep. of South
Email: yoonjun@snu.ac.kr

Background and aims: Antiviral treatment reduce the risk of developing hepatocellular carcinoma (HCC) in patients with chronic hepatitis B (CHB). However, there is a lack of high-quality evidence regarding the preventive effects of TAF on HCC. We evaluated the impact of TAF use after curative treatment on HCC recurrence.

Method: Patients who underwent surgery or radiofrequency ablation as a curative treatment for HCC were selected. Those patients who continued antiviral treatment with NAs (entecavir [ETV] or tenofovir disoproxil fumarate [TDF]) or switched to TAF were included. The primary outcome was HCC recurrence, and the time-varying effect of NA use on HCC recurrence was analyzed using various statistical methods.

Results: Among 2,794 consecutive patients with CHB who received curative treatment for HCC, 199 subsequently switched from ETV or TDF to TAF. After a median of 3.0 years, 1,303 patients (46.6%) experienced HCC recurrence. After propensity score matching (ratio 1:10), switching to TAF was not associated with an increased HCC recurrence (hazard ratio [HR], 1.00 [95% CI, 0.68–1.47]; $p=1.00$) by time-varying Cox analysis. Switching to TAF was not associated with HCC recurrence in subgroups of NA (HR, 1.06 [95% CI, 0.67–1.67]; $p=0.81$ for TDF, and 1.09 [95% CI, 0.51–2.33]; $p=0.82$ for ETV). Kaplan-Meier analysis showed comparable HCC recurrence-free survival between patients who switched to TAF and those who continued with their NA ($p=0.08$). Time-varying Cox analyses in various subgroups confirmed the primary findings.

Conclusion: TAF is as effective as TDF and ETV in preventing HCC recurrence after curative treatment.

Background and aims: Bulevirtide (BLV) has received conditional approval by the European Medicine Agency for the treatment of compensated chronic hepatitis D (CHD) in 2020 and has started to be used in some European countries including Greece, but there are limited real-life data to date. The aim of this study is to assess the efficacy and safety of BLV in CHD patients treated at Greek liver centers.

Method: All adult (>16 years old) patients with CHD followed at any of the participating centers who started BLV before the approvals (05-11/2023) of the HERACLIS_BLV_D study (NCT05928000) were included. All patients were treated with daily BLV subcutaneous injections of 2 mg, with or without concomitant use of a nucleoside (t) ide analogue (NA). Patients' monitoring was based on standard clinical practice according to the current recommendations for treatment of CHD. A predefined case report form was used for data collection. Serum HDV RNA during the study was determined by a polymerase chain reaction assay at a central lab (sensitivity: 100 IU/ml).

Results: In total, 76 patients were included; mean age: 50 ± 12 years, males: 37 (49%), born in Greece: 21 (28%), mean BMI: 25.4 ± 3.9 kg/m², mean liver stiffness (LS): 15.9 ± 9.5 kPa, cirrhosis: 45 (59%) (decompensated cirrhosis: 6/45), (peg-)interferon (IFN) in the past: 32 (42%) cases. No patient received combination of BLV with pegIFN; BLV alone was given in 9 (12%) and BLV plus a NA in 67 (88%) patients (ETV: 29, TDF: 35, TAF: 3). At 6 months, virological response (VR: serum HDV RNA undetectable or decline ≥2 log₁₀ IU/ml) was observed in 43 (24+19) (70.5%), biochemical response (BR: ALT ≤40 IU/L) in 43 (70.5%) and combined VR+BR in 32 (52.5%) of 61 patients. At 12 months, VR was observed in 40 (31+9) (83%), BR in 35 (73%) and combined VR+BR in 28 (58%) of 48 patients. Of the patients with no or partial VR (serum HDV RNA decline <1 or 1- <2 log₁₀ IU/ml), 11/18 and 7/8 cases achieved BR at 6 and 12 months, respectively; all cases without BR had reduced ALT and/or HDV RNA levels. Response rates did not differ between cirrhotic and non-cirrhotic patients. There was no drug-related serious adverse event and no patient discontinued BLV.

Conclusion: BLV therapy with or without NA is safe and effective in the treatment of CHD in real-life at Greek liver centers offering VR and BR rates even higher than those reported in clinical trials perhaps due to different patient characteristics.

WED-404

Comparable outcomes between Besifovir and other antiviral therapies in hepatocellular carcinoma development among patients with chronic hepatitis B

Jae Seung Lee¹, Sung Won Lee², Sang Gyune Kim³, Yeon Seok Seo⁴, Su Jong Yu⁵, Hyung Joon Yim⁶, Hye Won Lee¹, Mi Na Kim¹, Beom Kyung Kim¹, Jun Yong Park¹, Do Young Kim¹, Sang Hoon Ahn¹, Seung Up Kim¹. ¹Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South; ²Bucheon St. Mary's Hospital, The Catholic University of Korea School of Medicine, Department of Internal Medicine, Bucheon, Korea, Rep. of South; ³Soonchunhyang University Bucheon Hospital, Soonchunhyang University College of Medicine, Department of Internal Medicine,

Email: kskorea@yuhs.ac

Background and aims: Besifovir dipivoxil maleate (BSV), an acyclic nucleotide phosphonate, has potent antiviral efficacy against chronic hepatitis B (CHB), similar to other antiviral agents, such as entecavir (ETV), tenofovir disoproxil fumarate (TDF), and tenofovir alafenamide (TAF). This study compares outcomes between BSV and the other antiviral agents in hepatocellular carcinoma (HCC) development among patients with CHB.

Method: We conducted a retrospective cohort of 2,684 treatment-naïve patients with CHB who started their first-line antiviral therapy (AVT) between May 2017 and April 2022 with ETV (n = 840), TAF (n = 706), TDF (n = 666), or BSV (n = 472) at six tertiary medical institutions in South Korea. The incidence and hazard ratio (HR) were calculated using Kaplan-Meier and Cox regression analyses, respectively. Selection bias was minimized using inverse probability of treatment weighting (IPTW) and propensity score matching (PSM).

Results: Compared to the patients with other antiviral agents, BSV users showed a higher proportion of male patients (61.2% vs. 50.1–56.2%), alcohol intake >20 g/day (12.1% vs. 5.5–11.2%), and cirrhosis (37.9% vs. 30.5–34.3%). The incidence of HCC in BSV users (n = 6, 4.4 per 1000 person-years [PYs]) was similar to that in TAF users (8.5 per 1000 PYs, log-rank P = 0.111, HR 2.098, 95% confidence interval [CI] 0.827–5.324), however, significantly lower than those in ETV (n = 38, 12.7 per 1000 PYs, log-rank P = 0.026, HR 2.603, 95% CI 1.087–6.233) and TDF users (12.7 per 1000PYs, log-rank P = 0.035, HR 2.539, 95% CI 1.034–6.234). After applying 1:1:1:1 IPTW, the incidence of HCC in BSV users (n = 7 of 591, 3.8 per 1000 PYs) was similar to that in TAF users (n = 17 of 713, 8.6 per 1000 PYs, adjusted HR [aHR] 2.324, 95% CI 0.894–6.043), however, significantly lower than in ETV (n = 32 of 706, 12.4 per 1000 PYs, aHR 2.795 (95% CI 1.138–6.866, E-value 5.035) and TDF users (n = 34 of 674, 14.6 per 1000 PYs, aHR 3.322 (95% CI 1.334–8.274, E-value 6.099). Following separated 1:1 PSM (all 472 pairs), the incidence of HCC in BSV users (n = 6, 4.4 per 1000 PYs) was similar to that in TAF users (n = 12, 8.6 per 1000 PYs, log-rank P = 0.782, aHR 1.167, 95% CI 0.392–3.471), however, significantly lower than in ETV (n = 27, 15.2 per 1000 PYs, log-rank P = 0.025, aHR 2.978, 95% CI 1.024–8.659, E-value 5.404), and TDF users (n = 27, 16.6 per 1000 PYs, log-rank P = 0.025, aHR 3.000, 95% CI 1.090–8.254, E-value 5.449).

Conclusion: BSV showed comparable outcomes in HCC development among patients with CHB compared to TAF, ETV, and TDF. Given the small number of events and the relatively short follow-up duration observed in BSV users, further long-term analysis is warranted.

WED-405

Tenofovir disoproxil fumarate and tenofovir alafenamide interruption in hepatitis B and human immunodeficiency virus co-infected individuals in the United States: monitoring practices and incidence of hepatitis B reactivation or hepatitis flare

Douglas T. Dieterich¹, Laurence Brunet², Ricky Hsu^{3,4}, Karam Mounzer⁵, Gerald Pierone⁶, Michael Wohlfeiler⁷, Jennifer Fusco², Megan Dunbar⁸, Joshua Gruber⁸, Leland J. Email: laurence.brunet@epividian.com

POSTER PRESENTATIONS

Background and aims: Among HBV core antibody positive (cAb+) people with HIV, suppressive HBV treatment including either tenofovir disoproxil fumarate or tenofovir alafenamide (TDF/TAF) is recommended to prevent HBV reactivation. We describe TDF/TAF interruptions and HBV monitoring practices in the United States as well as assess the incidence of HBV reactivation and hepatitis flares during TDF/TAF interruptions in the OPERA cohort.

Method: All TDF/TAF interruptions among HBV surface antigen positive (sAg+) and/or cAb+ people with HIV were categorized by risk of reactivation (high: sAg+; moderate: sAg-/cAb+/HBV surface antibody negative [sAb-]; low: sAg-/cAb+/sAb+). Presence of HBV DNA, sAg and alanine transaminase (ALT) testing was assessed before (within ≤ 12 months) and during the interruption. Incidence of HBV reactivation and hepatitis flares (AASLD definitions) was assessed with Poisson regression.

Results: Of 31, 241 HBV/HIV co-infected people, 4, 901 (16%) had ≥ 1 interruption, for a total of 5, 643 interruptions (11% high, 19% moderate, 69% low risk); median duration: 83 weeks (IQR: 28–202). There were no DNA tests before (high: 55%, moderate: 97%, low: 97%) or during interruptions (high: 49%, moderate: 92%, low: 95%). There was no sAg test in 75% of high, 70% of moderate and 72% of low risk interruptions. HBV reactivation occurred in 103 high risk interruptions (16% overall; 32% of those with DNA tests) for an incidence rate [IR] of 9.59 per 100 person-years (95% CI: 7.91, 11.64). Reactivation occurred in 18 moderate risk interruptions (2% overall; 5% of those with DNA and/or sAg tests); IR: 0.58 (95% CI: 0.36, 0.91). Only 5 low risk interruptions resulted in HBV reactivation (0% overall; 0% of those with DNA and/or sAg tests); IR: 0.04 (95% CI: 0.02, 0.11). ALT tests were available before (high: 90%, moderate: 91%, low: 93%) and during interruptions (high: 98%, moderate: 100%, low: 99%). Hepatitis flares occurred in 60 (9%) high-risk interruptions (IR per 100 person-years: 5.28; 95% CI: 4.10, 6.80), 52 (5%) moderate-risk interruptions (IR: 1.72; 95% CI: 1.31, 2.26), and 132 (3%) low-risk interruptions (IR: 1.22; 95% CI: 1.03, 1.45).

Conclusion: In this large US cohort of sAg+ and/or cAb+ people with HIV receiving care in primary or HIV care clinics, TDF/TAF interruptions were common and lengthy, and HBV lab monitoring was sub-optimal, suggesting that primary and HIV care providers tend to be unaware of HBV status or overlook HBV monitoring and management in people with co-infection. While sAg+ individuals had the highest HBV reactivation and hepatitis flare risk, all were at-risk regardless of serology. Given infrequent testing, many reactivations were likely missed. Primary and HIV care providers need to incorporate HBV monitoring in their standard of care and proceed with caution if considering a TDF/TAF interruption for people with HBV/HIV co-infection.

DARING-B study: 5-year outcomes after nucleos(t)ide analogue (NA) cessation in Caucasian non-cirrhotic patients with HBsAg-negative chronic hepatitis B (CHBe-)

Margarita Papatheodoridi¹, Eirini Rigopoulou², Kalliopi Zachou², Emilia Hadziyannis³, Nikolaos Gatselis⁴, Ioannis Vlachogiannakos⁵, Spilios Manolakopoulos³, George Dalekos², George Papatheodoridis⁴.
¹Department of Gastroenterology, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece; ²Department of Medicine and Research Laboratory of Internal Medicine, Thessaly University Medical School, Larissa, Greece; ³2nd Department of Internal Medicine, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Hippokratio," Athens, Greece; ⁴Department of Gastroenterology, Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece; ⁵Medical School of National and Kapodistrian University of Athens, General Hospital of Athens "Laiko," Athens, Greece
Email: gepapath@med.uoa.gr

Background and aims: Cessation of long-term NA therapy has been regarded lately as a potential strategy that may increase the probability of functional cure, ie. HBsAg loss, in CHBe- patients, who should remain under close monitoring after stopping NA. The outcomes within 1–2 years post-NA have been well studied, but there are few data about longer outcomes. We aimed to assess the 5-year outcomes of our non-cirrhotic CHBe- patients included in the DARING-B study.

Method: DARING-B study prospectively enrolled 57 Caucasian patients (mean age: 58 ± 10 years, males: 37) without cirrhosis before NAs from 2 tertiary liver centers in Greece from 12/2015 to 03/2016. Patients with coinfection, cirrhosis, cancer or liver transplantation were excluded. Patient and treatment characteristics before and at end of NA therapy (EOT) were recorded. After NA cessation, patients were followed monthly for the first 3 months, every 2–3 months until completion of the first year and every 6 months thereafter. Predefined criteria for retreatment were used. Study end points were death or liver transplantation, liver decompensation, hepatocellular carcinoma (HCC), virological relapse (VR: HBV DNA >2000 IU/ml), clinical relapse (CR: HBV DNA >2,000 and ALT >2 \times ULN), retreatment and HBsAg loss.

Results: Median follow-up (FUP) was 5 (IQR: 3.6–6.5) years after EOT; only 4 patients were lost to FUP (<24 months). No patient died, required liver transplantation, developed liver decompensation or jaundice. Only one patient developed HCC diagnosed at 11 months (cumulative 1-year and 5-year incidence: 1.8%). At 1, 2, 3, 5 and 6 years post-NA, cumulative rates of VR were 70%, 74%, 75%, 75% and 75%, of CR were 33%, 35%, 39%, 39% and 39% and of retreatment were 26%, 30%, 38%, 45% and 45%, respectively. In total, 17/57 (30%) patients achieved HBsAg loss (2 after retreatment) with 1-, 2-, 3-, 5- and 6-year post-NA cumulative rates of 16%, 20%, 21%, 27% and 37%, respectively. EOT HBsAg ≤ 100 IU/ml was associated with more frequent HBsAg loss (HR:6.7, $P < 0.001$) and less frequent VR (HR:0.35, $P = 0.045$), whereas EOT HBsAg ≤ 1000 IU/ml was also associated with more frequent HBsAg loss (HR:16.7, $P = 0.007$) and less frequent CR (HR:0.44, $P = 0.057$) and retreatment (HR:0.33, $P = 0.009$).

Conclusion: Functional cure rates increase over the first 5–6 years after NA cessation in non-cirrhotic Caucasian patients with CHBe-, while risk of CR is mainly observed during the first year substantially decreasing thereafter.

WED-407

Characterization of hepatitis D virus RNA and hepatitis B surface antigen kinetics during pegylated interferon-alpha monotherapy: The D-LIVR study

Leeor Hershkovich¹, Harel Dahari¹, Scott Cotler¹, Ingrid Choong², Colin Hislop², Theo Heller³, Christopher Koh³, Jeffrey Glenn⁴, Tarik Asselah^{5,6}, Saeed Sadiq Hamid⁷, Ohad Etzion⁸.
¹Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, IL, United States; ²Eiger BioPharmaceuticals, Palo Alto, CA, United States; ³Liver Disease Branch, NIDDK, NIH, Bethesda, MD, United States; ⁴Division of Gastroenterology and Hepatology, Departments of Medicine, Microbiology and Immunology, Stanford School of Medicine, Stanford, CA, United States; ⁵Hôpital Beaujon, APHP, Clichy and the University of Paris-Cité, Paris, France; ⁶INSERM UMR1149, Paris, France; ⁷Aga Khan University, Karachi, Pakistan; ⁸Soroka University Medical Center, Beersheva, Israel
Email: harel.dahari@gmail.com

Background and aims: Current understanding of the kinetic profiles of hepatitis D virus (HDV) and hepatitis B surface antigen (HBsAg) during pegylated-interferon- α -2a (pegIFN) monotherapy is based on a 24-week analysis in 12 treated patients with HDV [Hepatology 2014;60:1902–1910]. We analyzed data from the Phase 3 D-LIVR study to further characterize HDV and HBsAg kinetics in patients treated with pegIFN alone.

Method: 52 participants in the D-LIVR study (NCT03719313) were treated with pegIFN and oral placebo for 48 weeks. HDV RNA was measured by Quest laboratories (lower limit of quantification, LLoQ <40 IU/ml; target not detected, TND <4 IU/ml) and HBsAg by Abbott Diagnostics at baseline, Weeks 1, 2, and 4 of therapy, and then every 4 weeks until end of therapy (EOT) and at 24 weeks of follow-up (EOFU). We defined monophasic (MP) pattern as a single HDV decline, biphasic (BP) pattern as an initial rapid decline followed by a slower decline, and triphasic (TP) pattern as two decline phases separated by an intermediary plateau. MP, BP, or TP patterns that were followed by a plateau (\geq LLOQ), termed flat partial response (FPR), biphasic FPR (BFPR), and staircase, respectively. A ≥ 2 -fold change in slope was used to distinguish between decline phases.

Results: 28 patients were excluded from analysis: 11 discontinued therapy, 9 had poor adherence or dose reductions, and 8 were non-responders (<1.6 log decline from baseline). Of the remaining 24 patients, 22 experienced an average delay of 8.0 ± 9.7 days before HDV declined from baseline, while 2 experienced very long delays of 20 and 28 weeks. Thereafter, we identified 6 HDV kinetic patterns: MP (n = 3), BP (n = 2), TP (n = 4) which were associated with reaching TND (n = 7), and those who plateaued above TND: FPR (n = 7), BFPR (n = 4), and staircase (n = 4). 12 (50%) patients had HDV rebound (>1.5 log IU/ml increase from nadir) after MP (n = 2/3), BP (n = 1/2), TP (n = 1/4), FPR (n = 4/7), BFPR (n = 3/4), and staircase (n = 1/4) declines, 23 ± 14 weeks into therapy. HDV rebound was not associated with HDV decline patterns. While HBsAg remained at baseline levels (3.6 ± 0.6 log IU/ml) for most patients (19/24), 5 patients (1MP, 1BP, 2TP, and 1 staircase who had a transient rebound before reaching TND) experienced a >1.5 log decline from baseline, all of whom achieved sustained TND until EOFU. Another patient (FPR) was HDV detectable at EOT but achieved TND at EOFU, while HBsAg remained at baseline level. A decline of >1.5 log in HBsAg from baseline by Week 36 had a 100% positive predictive value and a 95% negative predictive value for reaching HDV TND at EOFU.

Conclusion: Complex HDV decline patterns including triphasic and staircase were observed under pegIFN, that were not previously reported. The longer kinetic analysis (48 vs 24 weeks) identified on treatment HDV rebound in 50% of patients who initially responded to pegIFN. A >1.5 log HBsAg decline from baseline by Week 36 was associated HDV TND at EOFU.

WED-408

Factors influencing HBsAg clearance in children with chronic hepatitis B undergoing antiviral therapy: significance of age at treatment onset and HBeAg titer dynamics

Byung-Ho Choe¹, Sukjin Hong². ¹Kyungpook National University Children's Hospital, Daegu, Korea, Rep. of South; ²Daegu Catholic University Medical Center, Daegu, Korea, Rep. of South
Email: bhchoi@knu.ac.kr

Background and aims: This study aims to investigate the characteristics and determinants of HBsAg clearance in paediatric patients with HBeAg-positive chronic hepatitis B undergoing antiviral treatment in Korea, where genotype C is predominant.

Method: We enrolled 145 children diagnosed with chronic hepatitis B for antiviral therapy. Eligible patients had a history of HBsAg positivity for at least six months, elevated ALT levels more than twice the upper normal limit for six months or longer, or confirmation through liver biopsy. Treatment with nucleos (t)ide analogues (NA) was continued beyond complete remission (normalization of ALT levels, undetectable HBV DNA levels, and HBeAg seroconversion), followed by an additional NA consolidation therapy, at least 1 year. The duration of consolidation therapy was extended by the revision of EASL and APASL guideline to over 3 years, which was further extended if HBsAg titer decrease rapidly, in the expectation of achieving functional cure. Exclusion criteria included HBeAg-negative hepatitis B, spontaneous HBeAg seroconversion, or acute exacerbation of chronic hepatitis B from other causes. The study

analyzed various factors such as gender, pre-treatment ALT and HBV DNA levels, age at the initiation of treatment, and duration of treatment until complete remission, to identify variables that significantly influence HBsAg clearance. Additionally, we assessed the impact of the decrement velocity of HBeAg titer during NA treatment, categorizing the slope of the titer decrease into tertiles, and employing chi-square and logistic regression for analysis.

Results: In the study group of 145 patients, consisting of 80 males (55.2%) and 65 females (44.8%), with an average age of 8.0 ± 5.3 years (mean \pm SD) at the start of treatment, 35 (24%) achieved HBsAg clearance. The average duration from treatment initiation to clearance was 32.2 ± 39.2 months (mean \pm SD). Identified factors influencing HBsAg clearance included gender, pretreatment ALT levels, and age at the onset of treatment. Notably, female patients (p = 0.047) and those with higher pretreatment ALT levels (p = 0.046) showed better outcomes. Children under six years exhibited a significantly higher rate of clearance (p = 0.011), with a more rapid decrease in HBeAg titer also being a contributing factor (p = 0.015). All patients achieving HBsAg clearance eventually developed anti-HBs. No patient who had achieved functional cure has relapsed after discontinuation of NA.

Conclusion: In the treatment of HBeAg-positive chronic hepatitis B with NA, preschoolers or those demonstrating a rapid decline in HBeAg titer during NA treatment are more likely to achieve HBsAg clearance. For patients with Genotype C, particularly those younger than 6 years, a rapid decline in HBeAg titer may indicate the potential benefit of considering an extension of treatment until HBsAg loss is achieved.

WED-409

Improved HBV-RNA quantification by HBV-RNA reverse transcription droplet digital PCR

Bernhard Kleter¹, Sanne Gils¹, Joël Meyboom¹, Thierry Verbinnen², Oliver Lenz³, Leen-Jan Doorn¹. ¹Viroclinics-DDL, Rijswijk, Netherlands; ²Janssen Research and Development, Beerse, Belgium; ³Janssen Pharmaceutica, Beerse, Belgium, Beerse, Belgium
Email: bernhard.kleter@cerbaresearch.com

Background and aims: HBV-RNA is used as an exploratory biomarker in chronic HBV infection. HBV-RNA can be specifically detected in plasma, often even when HBV DNA is completely suppressed by e.g. nucleos (t)ide analogue treatment. The limit of detection (LOD) of the Viroclinics-DDL in-house fully validated HBV-RNA high sensitivity RT-qPCR assay is 25 copies/ml and a lower limit of quantification (LLOQ) 869 copies/ml (158 copies/qPCR). A HBV-RNA RT droplet digital PCR (ddPCR) assay was developed to improve sensitivity and extend the lower quantifiable range as ddPCR is most effective at low copy numbers of target.

Method: A comparison between our validated HBV-RNA high sensitivity RT-qPCR assay using 500 μ L of plasma and the HBV RNA RT-ddPCR test was performed using 133 plasma samples from patients with chronic hepatitis B participating in Janssen clinical trials, JADE (NCT03361956), OCTOPUS (NCT05275023) and PENGUIN (NCT04667104). HBV-RNA RT-ddPCR was performed with a plasma sample volume of 400 μ L in 81 samples and the remaining 52 samples were tested with 200 μ L due to sample volume shortage. From the OCTOPUS and PENGUIN studies baseline samples from virologically suppressed patients were tested (HBV DNA <20 IU/ml detected or negative). Samples from JADE were used to assess longitudinal HBV-RNA, HBV-DNA, HBsAg and HBcrAg profiles in 13 patients. In the JADE series, 28 samples were virologically suppressed.

Results: Based on HBV *in vitro* transcribed pregenomic RNA testing by RT-ddPCR the limit of blank is 0.73 copies/RT-ddPCR using Armbruster's approach. When testing 400 μ L plasma samples the 95% LOD by probit analysis was 2.7 copies/RT-ddPCR, corresponding to 16 copies/ml. The LLOQ was determined according to FDA-guidelines at 23.6 copies/RT-ddPCR, corresponding to 141 copies/

POSTER PRESENTATIONS

ml. In the panel of 133 samples concordant results by both assays were found in 74 (56%) samples. The qPCR and ddPCR assays scored below LOD in 65 (49%) and 39 (29%) samples, respectively. Four of the 39 samples were between LOD and LLOQ in the qPCR assay. By ddPCR, 49 samples were in the range between LOD and LLOQ. By qPCR, 24 of these 49 cases were also in the range between LOD and LLOQ and the remaining 25 samples were below LOD. In the quantifiable range of both assays, far more samples were found quantifiable by the ddPCR assay than by the qPCR assay, 45 (34%) and 15 (11%) respectively. All 15 qPCR quantifiable samples were also quantifiable by the ddPCR assay. Even 5 of them were quantifiable when testing 200 μ L plasma in the ddPCR assay.

Conclusion: Results show a clearly improved sensitivity and quantification of HBV RNA by the HBV-RNA RT-ddPCR assay. Due to the higher sensitivity in quantification of low HBV RNA concentrations, the response to treatment can be assessed for a longer period. This makes the HBV-RNA RT-ddPCR assay highly suitable for monitoring patients during antiviral treatment in clinical trials.

Sustained virological response after treatment with Bulevirtide in HDV patients. Data from the french multicenter real-life cohort

Victor de Lédighen¹, Karine Lacombe², Stanislas Pol², Laurent Alric³, Caroline Lascoux-Combe², Dulce Alfaite⁴, Marie-Noëlle Hilleret⁵, Nathalie Ganne-Carrié⁶, Jérôme Gournay⁷, Veronique Loustaud-Ratti⁸, Miroslava Subic-Levrero⁴, Fatoumata Coulibaly⁹, Estelle Le Pabic¹⁰, Christelle Tual¹⁰, Segolene Brichler⁶, Fabien Zoulim⁴. ¹CHU Bordeaux, pessac, France; ²APHP, Paris, France; ³CHU Toulouse, Toulouse, France; ⁴CHU Lyon, Lyon, France; ⁵CHU Grenoble, Grenoble, France; ⁶APHP, Bobigny, France; ⁷CHU Nantes, Nantes, France; ⁸CHU Limoges, Limoges, France; ⁹ANRS, Paris, France; ¹⁰CHU Rennes, Rennes, France

Email: victor.deledighen@chu-bordeaux.fr

Background and aims: Bulevirtide (BLV) has been approved for the treatment of patients with HDV infection. However, the long-term efficacy is unknown. The aim of this analysis was to evaluate the prevalence and factors associated with sustained virological response (SVR) in patients treated with BLV 2 mg daily with or without PEG-IFN α 2a in the French ANRS Buledelta cohort.

Method: Out of the 271 patients enrolled in the BuleDelta cohort, 30 patients with chronic HDV infection who stopped antiviral therapy were included in this analysis. Their characteristics were as follows: male 53.3%, mean age 45.7 \pm 11.5 years, mean liver stiffness measurement 12.2 \pm 8.3 kPa, cirrhosis 76.7%, median HDV-RNA 5.88 [Interquartile Range (IQR): 5.07; 6.56] log₁₀ (IU/ml), median qHBsAg 3544 [IQR: 878.8; 9356.0] IU/ml. Patients received 16.8 \pm 7.7 months of BLV 2 mg QD SC alone (N = 11) or in combination with PEG-IFN α once weekly (N = 19) according to physician's choice. All patients had undetectable or unquantifiable HDV RNA when stopping treatment. SVR was defined as persistently undetectable or unquantifiable HDV-RNA during their follow-up (FU).

Results: During the first 48 weeks FU, 17 patients (56.7%) experienced a relapse (quantifiable HDV RNA). Relapse was observed in 9/17 patients (52.9%) within the first 12 weeks FU. For the other 8, 5 relapsed at FU24 and 3 at FU36. None of the following factors was associated with SVR: age, gender, BLV duration, pegIFN treatment, cirrhosis, HDV RNA viral load, normal ALT at the end of treatment, time between the first unquantifiable HDV RNA and discontinuation of treatment, time between the start of treatment and the first unquantifiable HDV RNA. Three patients had qHBsAg below 100 IU/ml at the end of treatment (68.5, 66.6, 84.0, respectively). Among them, 2 experienced a relapse.

Conclusion: In patients who stopped treatment with BLV with or without pegIFN, SVR was observed in 43.3%. No factor was identified to be associated with SVR. Relapse was observed in more than 50% of patients during the first 12 weeks FU. Larger studies are needed to identify baseline or on-treatment predictive factors of SVR.

WED-411

The large (LHBs) and middle (MHBs) hepatitis B surface antigen are associated with response to bulevirtide or PEG-IFN α treatment in patients with chronic hepatitis Delta (CHD)

M. and A. Migliavacca" Center for Liver Disease, Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy

Email: Maria.pfefferkorn@medizin.uni-leipzig.de

Background and aims: CHD can be treated with the entry inhibitor bulevirtide (BLV) or with the immune modulator PEG-IFN α , but predicting treatment response remains uncertain. The composition of hepatitis B surface antigen (HBsAg), including large (L), middle (M), and small (S) forms, has been associated with HBsAg loss in hepatitis B virus (HBV) mono-infection. This study aimed to evaluate HBsAg composition in the natural course of CHD and its association with treatment response.

Method: 42 CHD patients receiving either 180 mg/week PEG-IFN α (n = 30) or 2 mg/day BLV (+ TDF 245 mg/day; n = 12) from 4 European centers (Leipzig, Berlin, Barcelona and Milan) were observed for a mean duration of 33.4 (12–156) months. Patients were divided according to their treatment response (decreases of HDV RNA or undetectability) after 12 months: I) Nonresponse defined as a <2 log decline in HDV RNA levels (NR; n = 17), II) partial response: a \geq 2 log IU/ml decline (n = 4), III) complete response: undetectable HDV RNA levels (n = 13) and VI) functional cure with HBsAg loss (n = 4). Six additional patients who underwent liver transplantation (after a mean time of 60 (2–72) months), with (2 with PEG-IFN and 2 with TDF treatment) or without (n = 1) treatment, were included. HBsAg composition, HDV RNA and HBV DNA were quantified in serum samples at time points BL, 6, 12, 18, and 24 months.

Results: Prior to treatment initiation, all groups showed similar levels of HDV RNA (6.5 log₁₀ IU/ml), total HBsAg (4.1 log₁₀ ng/ml), LHBs (2.8 log₁₀ ng/ml) and MHBs (2.9 log₁₀ ng/ml). Patients with subsequent transplantation or NR receiving either PEG-IFN α or BLV showed the highest proportions of MHBs (%) and LHBs (%) and showed no changes in either HBsAg levels, MHBs (%) and LHBs (%) during treatment (after 6 to 24 months), respectively. In contrast, patients with complete virologic response exhibited a decrease in MHBs (%) from 10.9 (6.9–26.5)% at BL to 2.1 (0–3.1)% after 12 months with PEG-IFN α (n = 7; p = 0.016) and from 10.5 (3.3–19.4)% at BL to 2.9 (2.3–3.5)% after 12 months with BLV (n = 6). Furthermore, establishing a BL-Cutoff for MHBs % and LHBs % showed that patients with <8% MHBs or <4.8% LHBs at the start of either PEG-IFN or BLV treatment had significantly higher likelihood to achieve a complete virologic response during treatment (60% vs. 14.3%; p < 0.005 for MHBs and 83% vs. 16% for LHBs; p < 0.005).

Conclusion: MHBs and LHBs may serve as valuable markers for monitoring treatment response to PEG-IFN α and BLV in patients with

CHD. However, these findings require validation in a larger patient cohort.

WED-412

Functional cure and prediction analysis of pegylated interferon alpha-2b in HBeAg negative chronic hepatitis B patients with normal ALT (Ice-breaking Project in China): an interim analysis update

Chong Zhang¹, Dawu Zeng², Dachuan Cai³, Xiulan Xue⁴, Lingyi Zhang⁵, Baojun Song⁶, Yufeng Gao⁷, Yan Huang⁸, Jia Shang⁹, Xiaofeng Wu¹⁰, Ying Zhang¹¹, Hua Jin¹², Hui Chen¹³, Hong Tang¹⁴, Xiaobo Lu¹⁵, Yujuan Guan¹⁶, Feng Min¹⁷, Liang Xu¹⁸, Gang Li¹⁹, Zhengguang Wang²⁰, Xiaoguang Dou¹. ¹Shengjing Hospital of China Medical University, Shenyang, China; ²The First Affiliated Hospital of Fujian Medical University, Fuzhou, China; ³The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China; ⁴The First Affiliated Hospital of Xiamen University, Xiamen, China; ⁵Lanzhou University Second Hospital, Lanzhou, China; ⁶The Sixth People's Hospital of Fushun, Fushun, China; ⁷The First Affiliated Hospital of Anhui Medical University, Hefei, China; ⁸Xiangya Hospital Central South University, Changsha, China; ⁹Henan Provincial People's Hospital, Zhengzhou, China; ¹⁰The Sixth People's Hospital of Shenyang, Shenyang, China; ¹¹Dalian Public Health Medical Center, Dalian, China; ¹²The Sixth People's Hospital of Benxi, Benxi, China; ¹³Hepatobiliary Hospital of Jilin, Changchun, China; ¹⁴West China Hospital of Sichuan University, Chengdu, China; ¹⁵The First Affiliated Hospital of Xinjiang Medical University, Urumchi, China; ¹⁶Guangzhou Eighth People's Hospital Guangzhou Medical University, Guangzhou, China; ¹⁷Army Seventy-three Army Hospital, Xiamen, China; ¹⁸Tianjin Second People's Hospital, Tianjin, China; ¹⁹Liaohu Oilfield General Hospital, Panjin, China; ²⁰Anshan City Hospital For Infectious Disease, Anshan, China
Email: zhangchong_83@163.com

Background and aims: In China, the proportion of Hepatitis B e antigen (HBeAg) negative chronic hepatitis B (CHB) patients is gradually increasing, which is related to the pre-C region mutation of long-term HBV infection. The disease progression of HBeAg negative CHB patients is fast, a large proportion of them have moderate or advanced liver inflammation or fibrosis, even if alanine aminotransferase (ALT) is normal, which requires timely antiviral treatment. The purpose of this study was to analyse the efficacy of pegylated interferon alpha-2b (PegIFN α -2b) in HBeAg negative CHB patients with normal ALT, and to explore the predictive factors of virological and serological responses. Preliminary data was presented at EASL2023 and here we update the latest results of this project.

Method: This is a multi-center, prospective, non-interventive, real-world clinical study conducted in China, involving 20 hospitals in 12 provinces or municipalities, which enrolled CHB patients with age of 18–60 years, Hepatitis B surface antigen (HBsAg) positive for more than 6 months, HBeAg negative, HBV DNA >20 IU/ml and normal ALT, without antiviral treatment history. PegIFN α -2b 180 μ g/week was applied on a voluntary basis. Examinations were performed every 12 weeks during treatment to monitor antiviral efficacy and adverse effects. The treatment strategy is adjusted according to the virological and serological response every 24 weeks, the total treatment course is not exceeded 96 weeks.

Results: A total of 249 patients were currently enrolled, and statistical analysis only be performed on 120 patients who completed PegIFN α -2b treatment. 72 (60.0%) were male, with an average age of 39.76 \pm 8.28 years (21–60 years). The median baseline HBV DNA and HBsAg were 6.87 \times 10² IU/ml (1.00 \times 10¹ ~ 7.62 \times 10⁶) and 297.91 IU/ml (0.12 ~ 32828.22) respectively. The mean duration of PegIFN α -2b treatment was 12.78 months. 43 patients (35.83%) achieved HBsAg loss, and their baseline HBsAg levels were significantly lower than those who did not achieve HBsAg loss (381.29 \pm 827.18 vs. 1872.31 \pm 4102.32, p < 0.001). 23 patients achieved HBsAg loss after a short course of 6–9 months, with lower baseline HBsAg levels compared to those achieved HBsAg loss after a course of \geq 12 months (96.34 \pm

141.54 vs. 708.98 \pm 1130.47, p < 0.001). Furthermore, HBsAg loss rate increased to 52.38% in patients with baseline HBV DNA <1000 IU/ml and HBsAg <500 IU/ml, and 66.67% in those with baseline HBV DNA <100 IU/ml and HBsAg <100 IU/ml. These patients all experienced functional cure with a short course of PegIFN α -2b treatment.

Conclusion: HBeAg negative CHB patients with normal ALT can achieve a high rate of functional cure by PegIFN α -2b therapy, especially for those with low baseline HBV DNA and HBsAg levels, only a short course of PegIFN α -2b treatment is required.

WED-413

10-year results under tenofovir disoproxil fumarate and entecavir in chronic hepatitis B; HBV clearance rare, disease outcomes good

Zülal İstemihan¹, Gamze Kemeç², Timurhan Becbeci², Okan Cetin², Sezen Genç Uluçeçen¹, Aynure Rüstemezade¹, Kanan Nuriyev¹, Bilger Çavuş¹, Asli Çifcibasi Örmeci¹, Filiz Akyuz¹, Kadir Demir¹, Fatih Beşişik¹, Sabahattin Kaymakoglu¹. ¹Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Gastroenterohepatology, Istanbul, Turkey; ²Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey
Email: kaymakoglus@hotmail.com

Background and aims: This study aims to investigate antiviral effectiveness, side effects, and disease outcomes in patients who have been using oral antivirals for a long-term in chronic hepatitis B (CHB). **Method:** Patients with CHB who had been using tenofovir disoproxil fumarate (TDF) or entecavir (ETV) for at least 10 years were included in this retrospective study. Co-infected patients, those receiving immunosuppressive therapy, and transplant patients were excluded.

Results: Of the total 173 patients (baseline mean age 43.44 \pm 11.74 years) in the study, 110 (63.6%) were men. 33 (19.1%) patients were cirrhotic, and HBeAg was negative in 131 (75.7%) patients at the beginning of treatment. 94 (54.3%) patients were treatment-naïve. 92 (53.2%) patients used TDF and 81 (46.8%) patients used ETV for a mean of 156.76 \pm 21.60 (120–204) months. HBV-DNA negativity (<10 IU/ml) was achieved in 100% of those who received ETV and in 95.5% of those who received TDF, and there was no statistical difference between them (p = 0.06). Patients who remained HBV-DNA positive were non-compliant with treatment. HBsAg became negative in only 4 (2.3%) patients, 2 of them developed anti-HBs. In the total group ALT normalization (<42 U/L) was observed in 96.8% of patients with elevated baseline ALT. 13 (39.4%) of 33 patients who were cirrhotic at baseline regressed to the noncirrhotic stage, in this group, platelets were significantly high (>150 10³/ μ l) before the treatment (p < 0.05). 8 (5.7%) of 140 noncirrhotic patients at baseline progressed to the cirrhotic stage. 7 (4%) of all patients decompensated. In the total group, FIB-4 and APRI scores decreased significantly under treatment (p = 0.009 and p = 0.000, respectively). Hepatocellular carcinoma (HCC) developed in 9 (5.2%) patients. All HCCs occurred after the 5th year of treatment. PAGE-B score was significantly higher in those who developed HCC (p = 0.009). HCC was significantly more common in treatment-naïve patients (p = 0.033). The age at HBV diagnosis was significantly higher in HCC patients (p = 0.023), but the most important risk factor for the development of HCC was cirrhosis at baseline. Cirrhosis increased the risk of HCC by 7.8 times. 8 (4.6%) patients died in the follow-up, and 2 were due to liver disease and the remaining non-liver disease. During follow-up, nephropathy (GFR <60 ml/min) developed in 13 (7.5%) patients, and hypophosphatemia (p < 2.5 mg/dL) developed in 19 (11%) patients. The rate of side effects in TDF recipients was significantly higher (p = 0.018).

Conclusion: At the end of 10 years, HBV-DNA negativity was achieved in almost all patients, and HBsAg sero-clearance was rarely achieved. Treatment-related side effects were more common in TDF. Nearly half of cirrhotic patients regressed to the noncirrhotic stage. Very few patients developed HCC and the 10-year mortality rate was similar to the general population.

Email: pieter.lampertico@unimi.it

Background and aims: Bulevirtide (BLV) is the only approved drug for patients with chronic hepatitis delta (CHD). In Italy this drug has been available since 2021, but no studies so far have addressed the demographic, virological and clinical features of patients treated with BLV monotherapy or in combination.

Method: Consecutive HDV patients with chronic hepatitis Delta (CHD) starting BLV 2 mg/day as monotherapy or in combination with pegIFNalpha were included in a multicenter real-life Italian study (D-SHIELD). Patients' characteristics before and during BLV treatment were collected. Virological, biochemical, clinical features were assessed.

Results: 257 patients with CHD from 26 centers were enrolled in this ongoing study. 99% received BLV 2 mg/day monotherapy: median age was 53 (28–81) years, 55% men, 96% of European origin, 83% with cirrhosis, 7% HIV-coinfected. Among patients with cirrhosis, 40% had varices, 10% had a history of HCC (active in 7%), 11% had a history of ascites (5% persistent), 3% with previous varices hemorrhage, 6% had decompensated (CPT-B) cirrhosis. At BLV start, median ALT were 79 (18–1, 074) U/L, liver stiffness measurement (LSM) 14.1 (4.0–68.1) kPa, platelets 112 (14–362) × 10³/mm³, 97% patients were on NUC therapy, 89% HBeAg negative. Median HDV RNA was 5.3 (1.5–8.2) log IU/ml and HBsAg 3.7 (0.6–4.7) log IU/ml. Patients with cirrhosis had lower HDV RNA values compared to non-cirrhotic patients (5.21 vs. 5.69 Log IU/ml, p=0.03), while no differences were observed concerning HBsAg (3.69 vs. 3.83 Log IU/ml, p=0.2) and ALT levels (80 U/L vs. 75, p=0.4).

Conclusion: D-SHIELD is the largest single country study on BLV treatment for CHD in Europe. Almost all Italian patients starting this new treatment option have been treated with 2 mg/day monotherapy. Most patients were European-born, with advanced liver disease, high viral load and elevated ALT levels.

WED-415

Effectiveness and safety analysis of switching to tenofovir alafenamide after entecavir or tenofovir treatment

Xue Liu¹, Zhihao Zhao¹, Xianggen Kong², Shiyu Cui², Xuemei Jiang². ¹Shandong university, Jinan, China; ²Shandong public health clinical center, Jinan, China
Email: shdixm@163.com

Background and aims: To investigate the effectiveness and safety of switching to tenofovir alafenamide (TAF) in patients with chronic viral hepatitis B after taking entecavir (ETV) or tenofovir (TDF) in a real-life setting.

Method: A total of 149 patients with chronic viral hepatitis B who had impaired renal function or were potentially at risk, or chronic viral hepatitis B with low viral load, were enrolled in the study from January 1, 2013 to May 1, 2023 by Shandong Public Health Clinical Center. The patients were divided into G1: ETV-TAF (61 patients) and G2: TDF-TAF (88 patients). All patients were followed up for at least 48 weeks. During the follow-up period, HBV DNA levels, HBsAg quantitative levels, liver function, renal function and blood lipids were collected, analyzed and compared between the two groups.

Results: At baseline, there were no statistical differences between the two groups in the rate of complete virologic response, quantitative HBsAg levels, or ALT levels. At 48 weeks of switching to TAF, both groups had significantly higher rates of complete virological response (G1 : 54.1% vs. 67.2%, $\chi^2 = 48.865$, P = 0.000; G2: 63.6% vs. 77.3%, $\chi^2 = 3.931$, P = 0.047) and significantly lower quantitative HBsAg levels (G1: z = -4.879, p = 0.000; G2: z = 3.174, p = 0.002) and lower mean ALT values (G1: z = 2.237, p = 0.000; G2: z = -2.571, p = 0.010) compared to baseline. In the both groups, eGFR levels increased compared with baseline, but there was no statistically difference at weeks 48. At baseline, 16 and 33 patients in the ETV-TAF group and TDF-TAF group, had an eGFR of less than 90 ml/min/1.73 m², and after 48 weeks of switching to TAF therapy, 6 patients in each group had an eGFR of greater than 90 ml/min/1.73 m². Median urinary beta-2 microglobulin levels improved significantly from baseline in both groups after 48 weeks of switching to TAF (G1: z = -2.785, p = 0.005; G2: z = -4.008, p = 0.000). There were no significant differences in triglyceride, LDL, total cholesterol, and HDL levels compared to

baseline at 24 and 48 weeks after switching in the ETV-TAF group, whereas in the TDF-TAF group at 48 weeks after switching, LDL and total cholesterol levels were higher compared to baseline, but there was no statistically difference in the proportion of patients with dyslipidaemia after 48 weeks of switching to TAF treatment in both the ETV-TAF group and the TDF-TAF group compared to baseline.

Conclusion: In patients with impaired renal function or potentially at risk for chronic hepatitis B, or chronic viral hepatitis B with low viral load, switching from ETV or TDF to TAF resulted in sustained enhancement of virologic response, sustained reduction in surface antigen levels, and improvement in ALT. Notably, patients experienced improvements in glomerular function and tubular markers.

WED-418

A national multicenter study on initial antiviral treatment preferences on chronic hepatitis B: Entecavir versus Tenofovir disoproxil fumarate

Email: tansuyamazhan@gmail.com

Background and aims: No current medications for chronic HBV treatment aim at eradicating the virus; therefore, the main goal of successful therapy is achieving functional cure through long-term or lifelong treatments. In selecting the initial antiviral drug, identifying comorbidities and monitoring possible long-term side effects are key considerations outlined in national and international guidelines. This study investigates whether there are statistically significant differences/differences in patient or disease parameters when a physician initiates entecavir (ETV) or tenofovir disoproxil fumarate (TDF) in a chronic HBV patient.

Method: Patient data was recorded by "electronic patient follow-up form. Treatment naïve, >18 years old, diagnosed with chronic HBV for at least 1 year since 2010 and initiated on antiviral therapy were included. Patients' data, including age and gender, age at diagnosis and treatment initiation, body mass index (BMI), the presence of comorbidities, liver disease activity, liver biopsy results, presence of cirrhosis and/or hepatic steatosis, the status of the virus via HBeAg positivity result, HBV-DNA levels; host factors including renal functions, cholesterol, triglyceride levels and basal bone mineral density (BMD), assessed using dual-energy X-ray absorptiometry (DEXA) test.

Results: The study involved 31 centers from Türkiye. Data from a total of 2, 259 (1, 391 were male (61.6%)) patients were analyzed. Among the participants, with 1, 270 patients (56.22%) initially opting for TDF

and 989 (43.78%) for ETV. ETV was preferred in males, while TDF was chosen more in females (p = 0.005). The mean of ages at diagnosis and treatment initiation for ETV were 40, ± 13, and 44, ± 13 and for TDF they were 36, ± 13, and 40, ± 12 (p < 0.001). TDF was more often chosen as the initial treatment in patients with lower BMI (median 25.7 versus 26.2 p = 0.001). The median initial creatinine level for TDF and ETV was 0.75 and 0.80 respectively (p < 0.001). The situation is similar for eGFR, where the median for the ETV group was 94.37, TDF group was 101.12. In patients with an initial eGFR value <60 (n: 36), upon reevaluation, physicians favored ETV as the initial drug choice (p < 0.001). BMD was assessed in 365 (16.3%) patients prior to treatment. DEXA tests were conducted in 116 (11.8%) and 249 (19.8%) patients who were to start ETV and TDF, respectively (p < 0.001).

Conclusion: Our study is an important national multicenter study with a broad patient series that clearly outlines the factors considered by infectious disease and hepatology specialists when initiating treatment for chronic HBV. Patient-related parameters; gender, age at diagnosis and treatment initiation of the disease, baseline renal functions, and the status and stage of the virus or liver disease have been found to be more important than the disease itself in drug selection.

WED-419

Comparative efficacy of standard and low-dose peginterferon-alpha2a in chronic delta hepatitis: a retrospective controlled study

Asim Qurbanov¹, Elvan Isik², İlker Turan², Galip Ersoz², Fulya Günsar², Zeki Karasu², Ulus Akarca². ¹Ege University, Faculty of Medicine, Department of Internal Medicine, İzmir, Turkey; ²Ege University, Faculty of Medicine, Department of Gastroenterology, İzmir, Turkey
Email: ulusakarca@gmail.com

Background and aims: Chronic delta hepatitis represents the most severe form of viral hepatitis, yet therapeutic options remain limited. While interferon-based therapies have been the cornerstone of treatment, their use is hampered by substantial side effects and marginal efficacy. This study assesses the effectiveness and tolerability of standard-dose versus low-dose peginterferon-alpha2a in patients with compensated chronic delta hepatitis.

Method: We conducted a retrospective analysis of patients treated with peginterferon-alpha2a at our center from 2000 to 2020. Patients receiving low-dose therapy (135 or 90 ug per week) over the past 5 years were compared with those treated with the standard dose (180 ug per week). End points included alanine aminotransferase (ALT) normalization and Delta RNA clearance.

Results: Our cohort comprised 45 patients, predominantly male (73%) with a mean age of 45.2 years. Treatment distribution was 20 patients on standard dose and 25 on low dose. Pretreatment transaminase levels, platelets counts, protrombin time, renal functions, HBV DNA and HDV RNA levels, rates of cirrhosis and prior interferon use were comparable. Cirrhosis was present in 38%, and 36% had prior interferon therapy. Median treatment durations in regular and low dose groups were 13 and 12 months, respectively. The complete response rates at 6, 12, and 18 months for standard and low-dose groups were 35%, 45%, 30% and 20%, 24%, 28%, respectively, with no significant differences. Side effect profiles were similar, though less hematological toxicity was noted in the low-dose group.

Conclusion: Low-dose peginterferon-alpha2a demonstrates comparable efficacy to the standard dose in chronic delta hepatitis, with a trend toward a better side effect profile. This approach may offer a cost-effective alternative in managing this challenging condition.

Viral Hepatitis B and D – New therapies, unapproved therapies or strategies

Dosing with the Capsid Assembly Modulator ALG-000184 in Untreated HBeAg Negative CHB Subjects Results in Potent Antiviral Effects Including Suppression of HBV DNA/RNA and Declines in HBcrAg Levels

Kosh Agarwal¹, Edward J. Gane², Man-Fung Yuen³, Christian Schwabe⁴, Alina Jucov⁵, Alexei Hacetean⁵, Min Wu⁶, Kha Le⁶, Maida Maderazo⁶, Lawrence Blatt⁶, Sushmita Chanda⁶, Tse-I Lin⁶, Matt McClure⁶. ¹King's College Hospital, Institute of Liver Studies, London, United Kingdom; ²Faculty of Medicine, University of Auckland, Auckland, New Zealand; ³Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; ⁴New Zealand Clinical Research Limited, Auckland, New Zealand; ⁵ARENIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova; ⁶Aligos Therapeutics, Inc., South San Francisco, United States Email: kosh.agarwal@kcl.ac.uk

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty (CAM-E) that inhibits viral replication and cccDNA establishment in vitro.

Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4 Cohort B, eligible treatment naïve or currently-not-treated HBeAg+ and HBeAg- CHB subjects are receiving open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. Previously, we reported that HBeAg+ subjects treated for ≤48 weeks in this cohort experienced potent antiviral effects as seen by declines in HBV DNA, RNA and multiple antigen levels (Yuen et al., AASLD 2023). Here we report for the first time antiviral and safety data in HBeAg- subjects who received 300 mg ALG-000184 monotherapy × ≤40 weeks.

Results: 11 HBeAg- subjects were enrolled with a mean age of 48 years; they were 55% male, 73% non-Asian and had a mean (SEM) BMI of 26 (1.1) kg/m². Subjects were infected with HBV genotype D (n = 7, 64%), B (n = 2, 18%), C (n = 1, 9%) and A (n = 1, 9%). At baseline, mean (SEM) viral marker values were: 4.3 (0.2) log₁₀ IU/ml for DNA, 2.0 (0.3) log₁₀ copies/ml for RNA, 3.5 (0.2) log₁₀ IU/ml for HBsAg and 3.1 (0.3) log₁₀ IU/ml for HBcrAg. During 300 mg ALG-000184 monotherapy, all subjects achieved undetectable HBV DNA (<10 IU/ml) within 20 weeks and RNA (<10 copies/ml) levels within 42 days. No viral breakthroughs have occurred. HBcrAg levels (iTACT-HBcrAg assay, LLOQ: <1.8 log₁₀ IU/ml) declined rapidly in the first 28 days of treatment followed by a slower downward trend. The maximum mean (SEM) and individual HBcrAg reductions through Week 40 were 0.5 (0.2) log₁₀ IU/ml and 0.7 log₁₀ IU/ml, respectively. HBcrAg reductions ≥0.5 log₁₀ IU/ml have been observed in 40% of subjects and one additional subject (with a low baseline level) became undetectable at Day 28, which has been maintained throughout treatment. No clinically significant decline was observed in HBsAg. The ALG-000184 safety profile remains favorable with no serious adverse events or discontinuations due to treatment-emergent adverse events (TEAEs) reported. Grade ≥3 TEAEs were reported in 2 subjects: an asymptomatic cholesterol and triglycerides increase (n = 1), which has been improving despite continued dosing, and one asymptomatic liver transaminase elevation (n = 1), which resolved despite continued dosing and was without clinically significant changes of liver synthetic function. This event was assessed as not being related to drug toxicity by an independent safety committee.

Conclusion: Consistent with its in vitro antiviral properties, dosing with ALG-000184 demonstrated dual antiviral effects in untreated HBeAg- CHB subjects: complete suppression of HBV DNA and RNA, suggesting inhibition of HBV replication, as well as reducing HBcrAg levels, indicating inhibition of cccDNA establishment/replenishment.

WED-362

Rapid hepatitis B surface antigen reduction in chronic hepatitis B virus infection: preliminary results from a phase I b study evaluating multiple ascending doses of HT-102, a neutralizing antibodies against hepatitis B surface antigen in chronic hepatitis B patients

Dong Wang¹, Shanzhong Zhang¹, Yanqin Ma¹, Lijuan Ding¹, Zhipeng Zhang¹, Ying Qu², Lungen Lu². ¹Suzhou Hepa Thera Biopharmaceutical Co.Ltd., Shanghai, China; ²Department of Gastroenterology, Shanghai General Hospital, Shanghai, China Email: wangdong@hepathera.com

Background and aims: HT-102 is a human monoclonal antibody targeting the conserved antigenic loop of hepatitis B surface antigen (HBsAg) with the potential to functions as 1) inhibition of hepatitis B virus (HBV) entry into cells, 2) elimination of virions and sub-viral particles for the treatment of chronic HBV infection. Single dose of HT-102 up to 600 mg were well tolerated in healthy subjects. Here, we reported preliminary Phase Ib data in subjects with chronic HBV infection.

Method: This was a randomized, double-blind, placebo-controlled, phase Ib, multiple ascending doses study of HT-102 administered via subcutaneous (SC) injection to subjects with chronic HBV infection. The 1b part enrolled subjects who were on nucleos (t)ide reverse transcriptase inhibitor (NRTI) therapy ≥2 months and had HBsAg >200 IU/ml, <3, 000 IU/ml with hepatitis B e antigen (HBeAg) negative at screening and HBV DNA <2, 000 IU/ml within 3 months before screening. Eligible patients were assigned to 50 mg, 150 mg, or 300 mg group to receive 5 SC HT-102 doses, every week for 4 weeks. Eight subjects per cohort were randomized (6:2) to receive HT-102 or placebo. All patients received NRTI treatment throughout the study. Patients were followed-up to Day 70 after the first HT-102 or placebo dosed. The protocol conformed to the Declaration of Helsinki guidelines and was approved by appropriate institutional review committee (s). Written informed consent was obtained prior to study procedures. Preliminary blinded data for the ongoing cohort evaluating 50 mg and 150 mg were presented.

Results: Sixteen subjects were enrolled in 50 mg, 150 mg of HT-102 or placebo and 12 subjects were randomized to receive 5 SC doses of HT-102, and 4 to receive placebo. Demographic and baseline characteristics were well balanced across cohorts (baseline HBsAg: 2.96 ± 0.35 log₁₀ IU/ml for 50 mg group; 2.82 ± 0.24 log₁₀ IU/ml for 150 mg group). In 50 mg group six subjects rapidly achieved mean 2.1 log₁₀ IU/ml decline in HBsAg from baseline at nadir and in 150 mg group six subjects achieved mean HBsAg decreases 2.4 log₁₀ IU/ml at nadir with sustained HBsAg declines for 4 weeks post last dose (4 subjects without HBsAg reduction were excluded in two cohorts). So far, all patients showed good safety and tolerability. All adverse event (AE)s were grade 1 or 2. No serious AEs or discontinuations due to AEs were reported. No subjects developed clinical or laboratory evidence of immune complex disease. Additional follow-up is ongoing.

Conclusion: Multiple doses of HT-102 50 mg or 150 mg was associated with rapid HBsAg reductions in the majority of subjects and greater HBsAg decline with longer sustained duration was observed in 150 mg group. Preliminary safety data suggested that HT-102 is generally well tolerated in CHB patients with NRTI. These early data support further evaluation of HT-102 as a potential functional cure for patients with chronic HBV infection.

WED-363

Promising preliminary data on preclinical efficacy with an innovative plasmid-launched live attenuated virus vaccine for chronic hepatitis B

Frederik Pauwels¹, Goele Bosmans¹, Sarah Provost¹, Thomas Vercruyse¹, Joeri Auwerx¹, Gregory Fanning¹, Mathieu Peeters¹, Wilfried Dalemans¹, Hanne Callewaert¹. ¹AstriVax, Leuven, Belgium
Email: frederik.pauwels@astrivax.com

Background and aims: AstriVax is developing a vaccine platform technology that is suitable for prophylactic and therapeutic applications and is based on a plasmid-launched live attenuated virus (PLLAV) encompassing flaviviruses, like yellow fever virus (YFV) 17D vaccine strain that can carry foreign antigens. The YFV vaccine is one of the most effective vaccines available, inducing long-lived humoral responses as well as strong cellular immunogenicity. With the therapeutic potential of our platform, we initiated development of a potential best-in-class vaccine for chronic hepatitis B infection, where the induction of effective and long-lasting CD8 T-cell responses is considered key in eliminating infected hepatocytes.

Method: The hepatitis B virus (HBV) core (HBc) was used as a model antigen to insert into the polyprotein encoding YFV 17D. The ability of this recombinant live-attenuated virus (LAV) to induce cellular immune responses against HBc was evaluated preclinically in a mouse model permissive for YFV replication (deficient in interferon (IFN) signaling). Given the complexity of the animal models that can be used with this platform we performed an initial assessment of the effect of the induced HBc-specific T-cells on viral parameters in AAV-HBV transduced C57BL/6 mice by adoptive transfer ± liver micro-environment modulation using a toll-like receptor (TLR) 9 agonist.

Results: Single injection of YFV-HBc PLLAV induced YFV and HBc specific T-cell responses in uninfected permissive mice. Similarly, an immunization with PLLAV-derived YFV-HBc LAV resulted in the detection of comparable numbers of IFN-gamma spot-forming cells upon stimulation with peptides for YFV and HBc antigen. Adjuvanted HBc protein prime followed by YFV-HBc LAV vaccination 15 days later increased the number of IFN-gamma secreting HBc-specific T-cells compared to YFV-HBc LAV only vaccination. Isolated splenocytes were then used for passive immunization of C57BL/6 mice with established AAV-HBV infection and high surface antigen (HBsAg) baseline (>4 log IU/ml), resulting in significant decreases in serum HBsAg, transient transaminase increase and a reduction in transduced hepatocytes positive for HBc when combined with a TLR9 agonist.

Conclusion: We found that a YFV PLLAV carrying an HBc antigen induced robust T-cell responses against HBc in a YFV-permissive mouse model. Furthermore, we were able to show that adoptive transfer of heterologous prime-boost generated T-cells resulted in a sustained decline of HBV persistence, despite high baseline HBsAg levels. These promising early efficacy data demonstrate the potential of YFV-vectored vaccines in inducing strong and effective T-cell responses, and warrant further preclinical characterization of the vaccine platform in direct vaccination settings and evaluation in human studies as part of therapeutic regimen for chronic hepatitis B.

WED-364

High-dimensional analysis of flow cytometry data reveals differences in post-treatment frequencies of naïve B cells, CD56dim natural killer cells, and terminally differentiated effector memory CD8+ T cells in responders versus non-responders to bepirovirsen

Thea Hogan¹, Eduardo Gomez Castaneda¹, Esther Perez Garcia¹, Ruth Barnard¹, Avijit Ray², Melanie Paff², Dickens Theodore³, Jennifer M. Singh². ¹GSK, Stevenage, United Kingdom; ²GSK, Collegeville, PA, United States; ³GSK, Durham, United States
Email: jennifer.m.singh@gsk.com

Background and aims: Bepirovirsen (BPV) is an unconjugated antisense oligonucleotide in development for the treatment of chronic hepatitis B virus (HBV) infection. In the Phase 2b B-Clear study, 9–10% of participants (pts) with chronic HBV infection who received BPV 300 mg for 24 weeks achieved the primary outcome (hepatitis B surface antigen and HBV DNA loss sustained for 24 weeks off-treatment). This post hoc investigation used high-dimensional analysis of flow cytometry data to understand the immunological landscape in pts who received BPV in B-Clear and determine whether cell frequencies and/or phenotypes differ with treatment time and/or response.

Method: Flow cytometric analysis was performed on 114 peripheral blood mononuclear cell samples from 47 pts using a 30-colour deep immunophenotyping panel. Cells were visualised in a reduced dimensionality space (UMAP) and metaclustered using FlowSOM. Metaclusters showing differential abundance according to the pts off-treatment response (e.g. primary outcome responder, null responder) or change in abundance relative to baseline (ARB) at 3 post-treatment timepoints (off-treatment Day 1, 78 and 162) were further evaluated for phenotypic annotation. Analyses were descriptive. Selection was made based on sample availability.

Results: Baseline demographics and disease characteristics were similar between those who had flow analysis and those that did not. The UMAP space revealed unique cell clusters between primary outcome responders and null responders. FlowSOM analysis identified 17 B cell, 18 natural killer (NK) cell and 14 T cell metaclusters. Two B cell metaclusters showed increased ARB in primary outcome responders versus null responders at all post-treatment timepoints; both metaclusters had a phenotype consistent with naïve B cells. One NK cell metacluster showed increased ARB at later timepoints (off-treatment Day 78 and 162) in primary outcome responders versus null responders, with a phenotype consistent with CD56dim NK cells. One T cell metacluster showed increased ARB at all post-treatment timepoints in primary outcome responders versus null responders, with phenotypes consistent with the terminally differentiated effector memory (TEMRA) CD8+ T cell subset (Granzyme B+ and T cell factor 1+) and T cells expressing Valpha 7.2+ T cell receptor.

Conclusion: This high-dimensional analysis revealed increases in the post-treatment abundance of naïve B cells, CD56^{dim} NK cells and TEMRA CD8+ T cells in responders versus non-responders to BPV in B-Clear. This analysis provides a first glance at the immunological landscape in pts treated with BPV. These data will shape analyses that will be applied to subsequent clinical trials to further elucidate the immune response in BPV-treated pts.

POSTER PRESENTATIONS

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty that inhibits viral replication and cccDNA establishment in vitro.

Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4, eligible treatment naïve or currently-not-treated HBeAg+ CHB subjects were either randomly assigned (3:1) to receive oral daily doses of 300 mg ALG-000184 or placebo + entecavir (ETV) × 12 weeks followed by open-label treatment with 300 mg ALG-000184 + ETV × ≤96 weeks (Cohort 2); or receive open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. Previously, we reported data of up to 48 weeks of treatment from these 2 cohorts, which showed greater reductions in HBV DNA/RNA and HBV antigens for ALG-000184 ± ETV vs. ETV alone. Here we report data after receiving 300 mg ALG-000184 ± ETV × ≤64 weeks.

Results: 22 HBeAg+/HBeAb- subjects were enrolled and received ≥12 weeks of treatment with ALG-000184 + ETV (n = 12) or ALG-000184 alone (n = 10). Mean (SEM) baseline viral marker values were HBV DNA 8.0 (0.2) log₁₀ IU/ml; HBV RNA 6.0 (0.3) log₁₀ copies/ml; HBSAg 4.3 (0.1) log₁₀ IU/ml; HBeAg 2.4 (0.1) log₁₀ PEI U/ml and HBcAg 8.3 (0.1) log₁₀ U/ml. After receiving 300 mg ALG-000184 ± ETV × ≤64 weeks, maximum (max) mean (SEM) reductions of HBV DNA and RNA were 7.1 (0.4) log₁₀ IU/ml and 4.7 (0.7) log₁₀ copies/ml. Of these subjects, 55% (n = 12) and 100% (n = 22) achieved <LLOQ for HBV DNA and RNA. No viral breakthrough has been observed in subjects receiving ALG-000184 alone. Mean (SEM) and max reductions in HBSAg, HBeAg, and HBcAg were: 1.2 (0.4) and 2.1 log₁₀ IU/ml, 1.8 (0.2) and 2.2 log₁₀ PEI U/ml, 2.3 (0.3) and 2.7 log₁₀ IU/ml, respectively. In parallel to HBeAg declines, mean (SEM) cut-off index (COI) of ROCHE Elecsys HBeAb assay (≤1 COI indicates anti-HBe positive) trended favorably, i.e. declining from baseline 5.2 (0.7) to 1.4 (0.1), suggestive of more non-HBeAg bound circulatory HBeAb. Two subjects have achieved HBeAb COI <1 along with substantial qHBeAg declines, which may suggest an ongoing transition to HBeAg seroconversion. Safety data continue to indicate ALG-000184 is well tolerated: no serious adverse events or discontinuations due to treatment-emergent adverse events (TEAEs) have been reported; Grade ≥3 TEAEs were reported in 7 subjects: uric acid increase (n = 1), eGFR decrease (n = 1), neutropenia (n = 1), cholesterol, triglycerides increase (n = 1) and ALT/AST elevations (n = 5). All resolved, improved or stabilized despite continued ALG-000184 dosing and were assessed by an independent safety committee as not being related to drug toxicity.

Conclusion: Treatment of HBeAg+ CHB subjects with ALG-000184 ± ETV continues to be well tolerated and lowers key viral markers over time. In parallel, an immunologic response may be emerging as evidenced by favorable trends for anti-HBeAb levels.

WED-366

Characterization of BJT-778, an anti-HBsAg neutralizing monoclonal antibody for treatment of hepatitis B virus and hepatitis D virus infections

Hilario Ramos¹, Ronald Alcala^{2,3,4}, Maud Michelet^{2,3,4}, Emmanuel Combe^{2,3,4}, Jerome Deval¹, Roy Grecko¹, Kevin Lin¹, Nancy Shulman¹, Fabien Zoulim^{2,3,4,5}, Keting Chu¹, Barbara Testoni^{2,3,4}, Hassan Javanbakht¹. ¹Bluejay Therapeutics, San Mateo, United States; ²INSERM U1052, CNRS UMR-5286, Cancer Research Center of Lyon (CRCL), Lyon, France; ³University of Lyon, Université Claude-Bernard (UCBL), Lyon, France; ⁴Hepatology Institute of Lyon, Lyon, France; ⁵Department of Hepatology, Croix Rousse Hospital, Hospices Civils de Lyon, Lyon, France
Email: hramos@bluejaytx.com

Background and aims: Chronic hepatitis B (CHB) is a major health problem around the world, impacting millions of people. Compared to CHB infection alone, co-infection with Hepatitis D Virus (HDV) is associated with more severe liver disease, causing faster progression to cirrhosis, hepatocellular carcinoma, and liver failure. In this

context, we have characterized BJT-778, a potent, pan-genotypic, fully human immunoglobulin G1 (IgG1) monoclonal antibody (mAb) with anti-HBsAg neutralizing properties, demonstrating its potential for the treatment of CHB and Chronic Hepatitis D (CHD).

Method: The binding affinity of BJT-778 to HBsAg was assessed using surface plasmon resonance. An enzyme-linked immunosorbent assay (ELISA) was used to assess the BJT-778 binding profile with representative HBsAg isolates from the major genotypes of HBV. The specificity of BJT-778 was evaluated using a Retrogenix human plasma membrane protein binding cell array, which includes 4,955 overexpressed human membrane proteins. Furthermore, in vitro neutralization was determined against HBV and HDV enveloped with HBsAg representing major HBV genotypes. The in vivo efficacy of BJT-778 was also investigated in a humanized Fah/Rag2/IL-2rγ triple knockout (FRG) mouse model of chronic HBV infection.

Results: BJT-778 is a potent, selective, fully human IgG1-neutralizing mAb that targets the antigenic loop present in all forms of HBsAg proteins. It binds with high affinity to the HBsAg protein, with K_d values ranging from 0.22 to 0.39 nM. BJT-778 demonstrates effective binding to HBsAg proteins across major HBV genotypes, with half-maximal inhibitory concentration (IC₅₀) values ranging from 0.02 to 0.07 nM. It neutralizes both HBV and HDV infections in vitro, exhibiting picomolar half-maximal effective concentration (EC₅₀) values. Furthermore, its neutralization activity is pan-genotypic, as evidenced by tests conducted with HDV enveloped with HBsAg from major genotypes. Additionally, BJT-778 is highly specific for HBsAg and did not show significant binding to any of the 4,955 tested human membrane proteins at a concentration of 2 μg/ml. In a humanized FRG mouse model, a 20 mg/kg dose of BJT-778 demonstrated rapid depletion of HBsAg from serum, achieving a reduction of 2.88₁₀ logs within 30 minutes post-antibody administration. In contrast, the IgG control, a negative control antibody, exhibited minimal activity against HBsAg in this model.

Conclusion: BJT-778 is a potent, selective, fully human IgG1-neutralizing mAb that can neutralize HBV and HDV infections in vitro and clear HBsAg-containing particles from serum in a humanized mouse model. BJT-778 is currently undergoing clinical evaluation in subjects with CHB and CHD infections.

WED-367

Viral sequence analysis of chronic hepatitis B (CHB) patients treated with the silencing RNA (siRNA) JNJ-3989 in the REEF-1 and REEF-2 clinical studies

Thierry Verbinen^{1,1}, Erkki Lathouwers¹, John Jerzorowski², Michael Biermer¹, Craig Grant³, Kosh Agarwal⁴, Man-Fung Yuen⁵, Sandra De Meyer¹, Oliver Lenz¹. ¹Janssen Pharmaceutica NV, Beerse, Belgium; ²Janssen Research and Development, LLC, Titusville, United States; ³Janssen RandD, High Wycombe, United Kingdom; ⁴Institute of Liver Studies, King's College Hospital, London, United Kingdom; ⁵Department of Medicine, The University of Hong Kong, Hong Kong, China
Email: tverbinn@its.jnj.com

Background and aims: JNJ-3989 is an siRNA composed of 2 triggers targeting the HBsAg and HBx protein open reading frame. Baseline (BL) polymorphisms in the target region complementary to positions 2–18 of the S- and X-trigger, considered potentially relevant for binding and activity, were present in 10% and 2.4% of not currently treated (NCT) REEF-1 patients, respectively, with no impact on JNJ-3989 induced HBsAg decline.

Here, viral sequence changes in the S-/X-trigger target regions were evaluated in patients with virologic relapse (VR; at least transient off-treatment increase in HBV DNA to >200 IU/ml from <LLOQ) after discontinuation of all treatment in REEF-1 (NCT03982186) and REEF-2 (NCT0412954).

Method: HBV DNA/RNA was extracted from on- and off-treatment plasma samples with sufficiently high HBV DNA/RNA levels and HBV genome was sequenced using Illumina sequencing. Nucleotide (nt)

variants were defined as changes versus the universal HBV reference sequence (sequence read frequency >15%).

Results: In REEF-1, VR occurred in 30/37 (81%) JNJ-3989 treated virologically suppressed (VS) patients stopping all treatment in REEF-2, in 54/77 (70%) JNJ-3989 treated and 39/40 (98%) NA-control arm patients, respectively. Across both studies 114/123 (93%) VS patients with VR had off-treatment HBV sequence data available. Variants at X-trigger target region positions of interest (POI) were more frequently observed off-treatment in JNJ-3989 treated VS patients than in NA-control arm VS patients with VR (56% and 5.7%, respectively). Variants at X-trigger target region POI 1794, 1785, and 1784 were observed off-treatment with a prevalence of 43%, 18% and 6.5%, respectively, which is higher than the prevalence of these variants off-treatment in either NA-only treated patients with VR (range: 0%–2.9%) or observed at baseline in REEF-1 NCT patients (range: 0%–1.2%). Variants at S-trigger target region POI were present off-treatment in 33% of JNJ-3989- and 19% of NA-only treated VS patients with VR and majority had variant at S-trigger POI 273, also frequently (10%) observed as at baseline in REEF-1 NCT patients. To assess if these variants observed during off-treatment follow-up were selected on-treatment, EOT samples from 30 NCT JNJ 3989-treated patients were evaluated using HBV RNA based sequencing and no emerging variants at S- or X-trigger target POI were detected. Off-treatment HBsAg kinetics did not differ between JNJ-3989 treated patients with and without variants in S-/X-trigger target POI observed during VR.

Conclusion: In JNJ-3989-treated patients who discontinued all treatment and experienced VR, variants within the X-trigger target region were frequently observed during VR but were not selected on-treatment, suggesting that these X-trigger variants developed off-treatment in JNJ-3989 treated patients. Presence of these variants did not impact off-treatment HBsAg kinetics.

WED-370

Bepirovirsen immune mechanism of action may potentiate infected hepatocyte killing: indirect evidence from B-together peripheral longitudinal biomarker analysis

Shilpy Joshi¹, Johannes Freudenberg¹, Jennifer M. Singh¹, Leigh Felton², Susan Dixon², Melanie Paff¹, Dickens Theodore³, Jill Walker⁴, ¹GSK, Collegeville, PA, United States; ²GSK, London, United Kingdom; ³GSK, Research Triangle Park, NC, United States; ⁴GSK, San Francisco, CA, United States
Email: shilpy.s.joshi@gsk.com

Background and aims: B-Together assessed efficacy and safety of sequential bepirovirsen (BPV), an unconjugated antisense oligonucleotide, followed by pegylated interferon (PegIFN) in participants (pts) with chronic hepatitis B virus (HBV) infection. Previously, we demonstrated that pts treated with BPV may experience transient alanine transaminase (ALT) increases. We investigated the role of BPV's immune mechanism of action (MoA) with respect to virological response (VR) and surrogate markers associated with hepatocyte cell death using peripheral longitudinal biomarker exploratory analysis.

Method: B-Together was a Phase 2b trial in 108 pts on stable nucleos (t)ide analogues. Pts were randomised (1:1) to receive BPV for 12 or 24 weeks followed by up to 24 weeks of PegIFN. The primary end point was the proportion of pts with hepatitis B surface antigen and HBV DNA below the limit of detection for 24 weeks after end of treatment (tx). Here, peripheral blood mononuclear cells, blood, and serum samples were subjected to flow cytometry, whole blood transcriptomics (WBT) and proteomics analyses, respectively. Relative expression was measured at baseline (BL) and post-BL at multiple timepoints during the BPV, PegIFN and off-tx phases. To determine differential expression, multivariate models were fit that included tx arms and VR subgroups.

Results: By Week 3, BPV led to a significant increase from BL in mean expression of serum proteins, including several cytokines, independent of arms or VR subgroups. These proteins showed enrichment in

immune effector response and apoptotic pathways. After 4 weeks of BPV, upward trends in proliferating activated CD8+ T-cells and B-cells were observed with a significant increase in mean expression from BL of some genes associated with proliferation in WBT independent of arms or response subgroups. After 7 weeks of BPV tx, a subset of proteins including liver and apoptosis-specific proteins showed increased abundance in serum and were more pronounced in BPV responders. Abundance of these proteins was highly correlated with ALT levels, which in turn was sometimes associated with transient low level HBV DNA elevations in serum; indirectly linking the observation to infected hepatocyte death.

Conclusion: BPV led to activation of the immune response in treated pts, providing support for an immune MoA. Three observations provide indirect evidence of a role for BPV in infected hepatocyte death: 1) presence of proliferating, activated adaptive immune cells in all response subgroups before rise in ALT; 2) increases in several liver and apoptosis-specific proteins in the serum concomitant with ALT elevations; 3) intermittent increase in HBV DNA during ALT elevations occurring more frequently in BPV responders than non-responders. Work is ongoing to further elucidate the multiple MoA of BPV and their roles in HBV functional cure.

Funding: GSK [209348/NCT04676724].

Background and aims: Functional cure of CHB will require suppression of viral replication, reduction of HBsAg and use of an immunomodulator such as pegylated interferon alfa-2a (IFN) to enhance HBV-specific immunity. Imdusiran (AB-729) is a GalNAc-conjugated single trigger siRNA that targets all HBV RNA transcripts and reduces all viral antigens including HBsAg. AB-729-201 is an ongoing Phase 2a study assessing 24 weeks of imdusiran followed by 12 or 24 weeks of IFN ± additional imdusiran doses in HBeAg-negative CHB subjects virally suppressed on nucleos (t)ide analogue (NA) therapy. Interim data through the end of the IFN treatment period (EOT) is available for all subjects.

Method: Forty-three subjects received imdusiran 60 mg every 8 weeks (wks) for 24 wks (4 doses) during the lead-in phase. After Wk

POSTER PRESENTATIONS

24, subjects were randomized to 1 of 4 sub-groups: A1 (24 wks IFN + 2 imdusiran doses + NA; N = 12), A2 (24 wks IFN + NA; N = 13), B1 (12 wks IFN + 1 imdusiran dose + NA; N = 8) or B2 (12 wks IFN + NA; N = 10). After completing IFN ± imdusiran treatment, subjects continued NA therapy for 24 wks and stopped NA therapy if ALT < 2 × upper limit of normal, HBV DNA undetectable and HBsAg < 100 IU/ml. Safety, antiviral and immunologic assessments were obtained. HBsAg was assessed via Roche Cobas Elecsys HBsAg II assay (lower limit of quantitation [LLOQ] = 0.05 IU/ml) and results < LLOQ were analyzed by Abbott HBsAg Next assay (sensitivity cutoff = 0.005 IU/ml).

Results: Baseline characteristics were described previously. All subjects have completed IFN dosing, and 18/43 subjects have been assessed for NA discontinuation (d/c) at Wk 76 or 64. In groups A1/A2, 7/25 (28%) subjects had HBsAg ≤ LLOQ at EOT (Wk 52) and 5/7 were confirmed to be non-reactive with the Abbott Next assay. All 7 subjects had concurrent anti-HBs levels > 10 IU/L, and 5/7 had levels > 100 IU/L. In groups B1/B2, 0/18 subjects had HBsAg ≤ LLOQ at EOT (Wk 40), although 2 reached < LLOQ during IFN treatment but subsequently rebounded. Group A1 had more profound HBsAg mean (±SE) log₁₀ change from baseline at EOT than other groups; A1 = -2.85 (0.41) log₁₀, A2 = -1.44 (0.43) log₁₀, B1 = -1.85 (0.38) log₁₀, and B2 = -1.68 (0.17) log₁₀. Imdusiran treatment was well-tolerated with no serious adverse events (AEs) or AEs leading to d/c; IFN-related AEs were like those reported previously. Nine of 18 subjects have stopped NA therapy; 1 subject has HBsAg and HBV DNA < LLOQ after 6 months off NA therapy suggestive of functional cure, and 1 subject restarted therapy after 8 wks due to confirmed HBV DNA > 20,000 IU/ml with normal ALT levels.

Conclusion: HBsAg ≤ LLOQ with detectable anti-HBs was observed at EOT in 28% of subjects who received 4 or 6 doses of imdusiran plus 24 weeks of IFN, but in 0 subjects who received 4 or 5 doses of imdusiran plus 12 weeks of IFN. The study remains ongoing and additional EOT data, durability of EOT HBsAg loss, and preliminary immunology data for a subset of study subjects will be presented.

WED-372

Downregulation of soluble FASLG as a potential mechanism of enhanced immune-related clearance of infected hepatocytes induced by JNJ-73763989 in HBeAg-negative virologically suppressed chronic hepatitis B patients

Simon Verheijden¹, Marianne Tuefferd¹, Marjolein Crabbe¹, Ewoud de Troyer¹, Thomas Vanwolleghem², Harry Janssen³, Michael Biermer⁴, Oliver Lenz¹. ¹Johnson and Johnson Innovative Medicine, Beerse, Belgium; ²Antwerp University Hospital, Edegem, Belgium; ³Centre for Liver Disease, Toronto, Canada; ⁴Johnson and Johnson Innovative Medicine, Neuss, Germany
Email: Sverhei1@its.jnj.com

Background and aims: Persistent exposure to hepatitis B surface antigen (HBsAg) in chronically infected hepatitis B patients can interfere with the host immune response to clear infected hepatocytes. JNJ-73763989 (JNJ-3989), a small interfering RNA (siRNA) targeting all HBV ribonucleic acid (RNA) transcripts resulting in profound HBV surface antigen (HBsAg) reductions, is currently under development for treatment of chronic hepatitis B. Here, we evaluated serum proteome changes during JNJ-3989 treatment across two clinical studies, to evaluate the effect of JNJ-3989 on host responses. **Method:** Serum was collected from HBeAg-negative, virologically suppressed (VS) patients from two phase 2 studies with 48 weeks of JNJ-3989 based treatment: REEF-1 (n = 44) and REEF-2 (n = 35). Soluble serum proteins were evaluated with Olink Explore[®], a high-throughput protein biomarker discovery platform used before in chronic hepatitis B studies. A mixed effects model was applied to assess serum protein changes during JNJ-3989 based treatment. Significantly affected proteins were explored by evaluating overlap between both studies and association with HBsAg levels.

Results: 84/1460 (5.8%) proteins (REEF-1) and 669/2943 (22.7%) proteins (REEF-2) were differentially expressed comparing baseline

with on-treatment. 62 proteins were consistently changed under JNJ-3989 based treatment across both studies. Network analysis showed apoptosis (FAS, FASLG, TNFRSF10B, CTSE, CTSL) and glyoxylate/dicarboxylate, sphingolipid and carbohydrate metabolism (AGXT, SHMT1, HAO1, SMPD1, ASAH2, ENPP7) as the main pathways affected during JNJ-3989 treatment. Most of the upregulated proteins (56/62; 90.3%) were liver-enriched cytoplasmic proteins involved in hepatocyte metabolism, suggesting increased hepatocyte death. Soluble Fas Ligand (FASLG), a key protein involved in cell death induced by cytotoxic T/NK cells was downregulated in both studies and at multiple timepoints. Strikingly, we did not observe any association with FASLG levels and HBsAg levels at baseline or on-treatment. Only 1/62 protein (PON2) was associated with HBsAg levels at baseline, whereas 4/62 proteins (AGXT, C19orf12, CTSE, SEZ6L) were negatively associated with HBsAg levels at W48 of treatment, but not at baseline. **Conclusion:** Serum proteomic analyses in VS HBeAg negative patients across two clinical studies showed that JNJ-3989 treatment reduces soluble FASLG and increases serum levels of intracellular hepatocyte proteins, suggestive of increased hepatocyte cell death. As soluble FASLG can interfere with the pro-apoptotic action of cytotoxic T/NK cells through steric hinderance of the membrane bound FAS/FASLG interaction, these data suggest JNJ-3989 treatment might improve clearance of infected hepatocytes by cytotoxic immune cells through restoration of FAS/FASLG mediated apoptotic signaling.

WED-373-YI

Epidemiological data and clinical profiles of hepatitis B surface antigen levels in chronic hepatitis B: implications for novel drug development

Rex Wan-Hin Hui¹, Trevor Kwan-Hung Wu¹, Ryan Hin-Man Leung¹, Lung Yi Loey Mak¹, Danny Ka-Ho Wong¹, James Fung¹, Wai-Kay Seto¹, Man-Fung Yuen¹. ¹The University of Hong Kong, Hong Kong, Hong Kong
Email: huirex@connect.hku.hk

Background and aims: Quantitative hepatitis B surface antigen (qHBsAg) is an important biomarker in the management of chronic hepatitis B (CHB). qHBsAg < 100 IU/ml is associated with spontaneous HBsAg seroclearance, whereas qHBsAg < 1000 IU/ml is associated with improved treatment responses to different novel HBV antivirals. Despite its prognostic role, epidemiological data and clinical profiles of qHBsAg in CHB is not well-defined.

Method: We performed a large cohort study on CHB patients who received qHBsAg testing between 2009 and 2020 in Queen Mary Hospital, Hong Kong. Serum qHBsAg was measured by the Elecsys HBsAg II assay (lower limit of detection: 0.05 IU/ml). Patients with undetectable qHBsAg were excluded from this analysis. Tests for serum HBV DNA, hepatitis B e-antigen (HBeAg) and liver biochemistry were measured on the same samples. We reported proportions of patients with different qHBsAg levels and analysed factors associated with qHBsAg < 1000 and < 100 IU/ml respectively.

Results: This analysis included 4,293 patients (62.5% male; mean age 48.0 ± 12.9; 20.4% HBeAg positive; 45.2% on nucleos(t)ide analogue [NUC]). The median qHBsAg level was 627.2 (interquartile range 117.0–1868.0) IU/ml. The proportion of patients in each qHBsAg strata were 8.3% with qHBsAg < 10 IU/ml, 15.0% with 10–100 IU/ml, 35.5% with 100–1000 IU/ml, 21.5% with 1000–3000 IU/ml, 5.3% with 3000–5000 IU/ml, and 14.4% with ≥ 5000 IU/ml. This corresponds to 58.8% and 23.3% of patients with qHBsAg < 1000 IU/ml and < 100 IU/ml respectively. In treatment-naïve patients (n = 2,354), 47.1%, 23.0% and 10.1% of patients had qHBsAg < 1000 IU/ml, < 100 IU/ml and < 10 IU/ml respectively. In NUC-treated patients (n = 1,939, median NUC duration 5.4 [3.6–8.1] years), 73.0%, 23.7% and 6.1% of patients had qHBsAg < 1000 IU/ml, < 100 IU/ml and 10 IU/ml respectively. Female sex (829.7 vs 518.6 IU/ml in males), treatment-naïve status (1242.0 vs 357.7 IU/ml in NUC-treated patients) and HBeAg-positive status (2398.0 vs 398.2 IU/ml in HBeAg-negative) were associated with higher qHBsAg levels respectively (all p < 0.001). Older age correlated with lower qHBsAg (r = -0.157, p < 0.001). Serum HBV DNA (r = 0.188),

alanine aminotransferase ($r=0.130$) and bilirubin ($r=0.031$) all weakly correlated with qHBsAg (all $p < 0.05$). In both treatment-naïve and NUC-treated groups, age and HBeAg status were independent predictors of qHBsAg < 1000 IU/ml and < 100 IU/ml respectively (all $p < 0.001$).

Conclusion: Over 40% of CHB patients have qHBsAg > 1000 IU/ml. These patients are unlikely to have spontaneous HBsAg seroclearance, and will also have suboptimal responses to novel HBV antivirals, highlighting a potential treatment gap. Demographic, viral and treatment factors were associated with qHBsAg. Targeted strategies using different combination therapies and treatment durations for patients with specific characteristics should be studied in future clinical trials.

WED-374

Safety, tolerability, and pharmacokinetics of BJT-778, a monoclonal antibody for treatment of chronic hepatitis B and chronic hepatitis D, following single ascending doses in healthy volunteers

Edward J. Gane¹, Christian Schwabe², Patrick Smith³, Courtney Moc Willeford³, Carole Moore⁴, Roy Grecko⁴, Keting Chu⁵, Hassan Javanbakht⁴, Nancy Shulman^{4,4}. ¹University of Auckland, New Zealand Clinical Research, Auckland, New Zealand; ²New Zealand Clinical Research, Auckland, New Zealand; ³Certara, Inc., Princeton, NJ, United States; ⁴Bluejay Therapeutics, Inc., San Mateo, CA, United States; ⁵Bluejay Therapeutics, Inc., San Mateo, Inc, United States
Email: edgane@adhb.govt.nz

Background and aims: BJT-778 is a potent, selective, fully human immunoglobulin G1-neutralizing monoclonal antibody that targets the antigenic loop present in all forms of hepatitis B surface antigen proteins, which are the key viral protein responsible for recognition, binding, and entry of hepatitis B virus (HBV) and hepatitis delta virus (HDV) virions to hepatocytes. In addition to preventing hepatocyte infection, BJT-778 should facilitate both clearance of circulating virions and presentation to antigen presenting cells, thereby enhancing HBV-specific T-cell responses. BJT-778-001 is an ongoing 2-part study evaluating the safety, tolerability, pharmacokinetics (PK), and antiviral activity of BJT-778 in healthy volunteers (HVs) and in subjects with chronic HBV (CHB) including those with chronic HDV (CHD) infection.

Method: Part 1 of the study is a Phase 1a/1b double-blind, randomized, placebo-controlled single-ascending-dose in HVs (Cohort A), CHB and CHD subjects (Cohorts B-D). Subjects were randomized 6:2 to receive a single subcutaneous dose of BJT-778 75 mg, 300 mg, or 900 mg, or placebo. Part 2 of the study is a multicenter, open-label Phase 2a multiple dose study in CHB and CHD subjects. Preliminary data from Cohort A of Part 1 are reported here.

Results: Among the 24 HVs in Cohort A, 18 HVs were randomized to receive BJT-778. Maximum plasma concentrations (C_{max}) of BJT-778 were achieved at 7 days post-dose with mean elimination half-lives of approximately 27 to 37 days across all dose levels. The C_{max} and area under the plasma concentration-time curve from time 0 to infinity (AUC_{inf}) increased proportionally between 75 mg to 900 mg and mean values ranged from 6.74 to 87.1 ug/ml (C_{max}) and 333 to 5070 day*ug/ml (AUC_{inf}). In vitro, the half maximal effective concentration (EC₅₀) values for neutralization of HBV and HDV infections were 0.09 and 0.01 nM, respectively, and plasma concentrations consistently exceeded the EC₅₀ for all doses levels over the 84-day sampling period. Preliminary safety data are still under blinded review. Among the 24 HVs who received either BJT-778 or placebo, six adverse events (AEs) in five subjects were considered as potentially related to treatment. These events include injection site bruising (n=4), injection site swelling (n=1), and fatigue (n=1), all Grade 1 (mild). There were no serious AEs, Grade 3/4 AEs, or significant laboratory abnormalities reported.

Conclusion: The PK of BJT-778 administered subcutaneously increased dose-proportionally up to the highest dose, 900 mg. The long half-life and sustained plasma concentration surpassing the EC₅₀ support the convenient clinical dosing schedules and suggest that dose levels are within the therapeutic range, respectively. All doses were safe and well tolerated. Following these favorable safety and PK results, the proof-of-concept Phase 1b study has been initiated in patients with CHB and CHD.

WED-375

VTP-300 immunotherapeutic, plus low dose PD-1 inhibitor, nivolumab, continues to show meaningful, sustained reductions in HBsAg levels

Dereck Tait¹, Louise Bussey¹, Radka Kolenovska¹, Matt Downs¹, Katie Anderson¹, Antonella Vardeu¹, Man-Fung Yuen², Wan-Long Chuang³, Chun-Jen Liu⁴, Apinya Leerapun⁵, Pisit Tangkijvanich⁶. ¹Barinthus Biotherapeutics, Didcot, Oxford, United Kingdom; ²Queen Mary Hospital, Hong Kong, Hong Kong; ³Kaohsiung Medical University ChungHuo Memorial Hospital, Kaohsiung City, Taiwan; ⁴National Taiwan University Hospital, Taipei City, Taiwan; ⁵Maharaj Nakorn Chiang Mai Hospital, Chiang Mai, Thailand; ⁶King Chulalongkorn Memorial Hospital, Bangkok, Thailand
Email: dereck.tait@barinthusbio.com

Background and aims: Functional cure of chronic hepatitis B (CHB) is considered to be achieved when HBsAg and HBV DNA are undetectable in the blood and the immune system maintains this state. VTP-300 is a targeted immunotherapeutic consisting of two viral vectors, ChAdOx1 and MVA, containing consensus HBV genotype C sequences; full length surface, modified polymerase, and core sequences. Study HBV003 is an ongoing open-label, randomised, Phase 2b study to assess the safety, immunogenicity, and efficacy of different regimens of VTP-300 in combination with low dose nivolumab in participants with non-cirrhotic CHB who are on suppressive therapy with nucleos (t)ide analogues (NUC).

Method: Up to 120 participants with HBsAg ≥ 10 and < 4000 IU/ml are being enrolled into three groups in HBV003. The protocol was amended to alter the HBsAg inclusion criteria to ≥ 10 and < 200 IU/ml and to exclude participants considered to be at risk of auto-immune thyroiditis. All three groups received ChAdOx1-HBV on Day 1, which was followed by: MVA-HBV and low dose nivolumab on Day 29 in Group 1; MVA-HBV and low-dose nivolumab on Days 29 and 85 in Group 2; MVA-HBV on Days 29 and 85 with low-dose nivolumab administered on Day 36 in Group 3. NUCs may be discontinued if participants meet certain criteria. Safety data, immunology data, and HBV marker data are collected throughout the study to Day 336.

Results: 76 participants have currently been recruited, of whom 24 (32%) have baseline HBsAg levels ≤ 200 IU/ml. Day 169 data, 6 months after first dose of study drug, are currently available from 70 participants. In total, HBsAg log reductions at Day 169 of ≥ 0.5 log and ≥ 1 log in participants with HBsAg ≤ 200 IU/ml were observed in 59% and 27% participants, respectively, compared to 13% and 2% in participants with HBsAg levels > 200 IU/ml. 18 participants have met the eligibility criteria for NUC discontinuation and four have discontinued NUCs. Three participants (two in Group 2 and one in Group 1) have undetectable HBV DNA and HBsAg at Day 113, Day 169, and 10 weeks post-NUC discontinuation. One unrelated SAE has been reported, and thyroid dysfunction was reported in seven participants. Further accumulating data, including safety, HBV markers, NUC discontinuation, and immunology data will be presented.

Conclusion: Preliminary safety data suggest that VTP-300 in combination with low dose nivolumab has been generally well tolerated and has resulted in meaningful, sustained HBsAg reductions, particularly in participants with baseline HBsAg levels ≤ 200 IU/ml. We believe that VTP-300 is a promising immunotherapeutic candidate for enhancing CHB functional cure rates. VTP-300 is also being investigated in combination with a siRNA inhibitor, imdusiran.

Tobevibart (VIR-3434), a monoclonal antibody, resistance analysis in participants with chronic HBV: Results from a Phase 1 single dose study

Hasan Imam¹, Julia di Iulio¹, Thanh Quach¹, Yi-Pei Chen¹, Sonia Maciejewski¹, Keith Boundy¹, Andre Arizpe¹, Kosh Agarwal², Man-Fung Yuen³, Andrea Cathcart¹, Gregory Camus¹. ¹Vir Biotechnology, Inc., San Francisco, United States; ²King's College Hospital, London, United Kingdom; ³Queen Mary Hospital, The University of Hong Kong, Hong Kong SAR, Hong Kong
Email: gcamus@vir.bio

Background and aims: Tobevibart (VIR-3434) is an investigational Fc-engineered human monoclonal antibody targeting the conserved antigenic loop of HBsAg in development for the treatment of chronic hepatitis B (CHB) and chronic hepatitis D. Here, we report hepatitis B virus (HBV) sequencing results in participants with CHB given a single dose of tobevibart, before and after treatment.

Method: VIR-3434-1002 was a randomized, double-blind, placebo-controlled phase 1 single ascending dose study that evaluated the safety, tolerability, and antiviral activity of tobevibart. In Part D, participants with CHB were not on NRTIs, had baseline HBV DNA ≥ 1000 IU/ml, and received a single dose of 75 or 300 mg of tobevibart subcutaneously. The whole HBV virus genome was sequenced in these viremic participants, both at baseline and following tobevibart treatment. HBV genotypes were determined for each participant based on phylogenetic analysis of the viral sequence data and genotype specific HBV reference sequences. Viral sequences at baseline were aligned to their genotype specific reference sequences to identify substitutions from reference. Viral sequences post-treatment were compared to their corresponding baseline sequences to identify potential emergent substitutions. *In vitro* phenotypic analysis of substitutions in the tobevibart binding site are underway.

Results: Twelve participants enrolled in Part D received a single dose of either 75 or 300 mg tobevibart, while 4 participants were randomized to the placebo group. HBV sequencing was successful in all 16 participants in the tobevibart treatment or placebo groups at both baseline and postbaseline timepoints. Out of the 16 participants enrolled in Part D, 4, 2, 4, and 6 participants had HBV genotypes A, B, C, and D, respectively. At baseline, 2 participants each in the tobevibart 75 mg, 300 mg, and placebo groups had substitutions in the tobevibart binding site when compared to the relevant genotype reference sequences. No binding site emergent substitutions relative to baseline were identified in any of the 12 participants who received tobevibart. Four of these participants had emergent substitutions in the HBV S gene, outside the tobevibart binding site. All of these emergent substitutions in the S gene were found in only 1 participant each. Phenotypic analysis of the binding site substitutions from reference will be presented.

Conclusion: Viral sequencing analysis of 12 participants who received a single dose of tobevibart showed no treatment-emergent substitutions in the tobevibart binding site, and no emergent substitution in the S gene was found in more than 1 participant at any dose evaluated. These findings suggest no emergence of resistance following a single dose of tobevibart, and support its continued development for functional cure of CHB and treatment of HDV.

WED-377

Preclinical profiling of ABI-6250, a novel orally bioavailable small-molecule therapeutic candidate for the treatment of chronic hepatitis D

Marc P. Windisch¹, Nuruddin Unchwaniwala¹, Jinghu Carl Li¹, Yanhong Zhu¹, Heidi Contreras¹, Dinara Azimova¹, Francielle Tramontini Gomes de Sousa¹, Joseph Tan¹, Kirsten Stray¹, Ariel Tang¹, Peter Haggie¹, Gene Schulze¹, Michael Shen¹, Jiaxin Yu¹, Michel Perron¹, Michael A. Walker¹, William E. Delaney¹, Min Zhong¹.

¹Assembly Biosciences, Inc., South San Francisco, United States
Email: mwindisch@assemblybio.com

Background and aims: Chronic hepatitis D virus infection (cHDV) is the most severe form of viral hepatitis. Bulevirtide (BLV), a peptide preventing the binding of HDV to sodium taurocholate co-transporting polypeptide (NTCP), the viral entry receptor, is approved in Europe for the treatment of cHDV. Clinical trials demonstrated the safety and efficacy of injectable BLV. Here we describe the preclinical profiling of a new therapeutic candidate, ABI-6250, a novel orally bioavailable small-molecule HDV entry inhibitor.

Method: ABI-6250 HDV half-maximal effective concentration (EC_{50}) and protein-adjusted EC_{50} were determined in pretreated HepG2-NTCP cells by measuring intracellular hepatitis D antigen (HDAG) following infection. ABI-6250's competitive inhibition of hepatitis B virus (HBV) preS1 NTCP binding, impact on NTCP-dependent bile acid (BA) uptake, and selectivity against a broad panel of BA transporters were assessed by monitoring fluorescently labeled preS1 binding and BA uptake in human embryonic kidney cells. Metabolic stability was assessed in liver microsomes (LMs) from multiple species. Oral bioavailability was determined in both rodents and non-human primates (NHPs). Dose-escalating pharmacokinetic/pharmacodynamic (PK/PD) and tolerability studies were performed in NHPs and rats, monitoring drug exposure and BA elevations.

Results: ABI-6250 potently inhibits the infection of all tested HDV genotypes (1–3), with HBV genotype B or D envelopes (HDV EC_{50} =5–16 nM), and a protein-adjusted EC_{50} increase of approximately 35-fold in HDV genotype 3 enveloped with HBV genotype D. ABI-6250 inhibits preS1 binding (half-maximal inhibitory concentration [IC_{50}]=22 nM) and NTCP-dependent BA uptake (IC_{50} =11 nM), demonstrating the target is NTCP. Furthermore, ABI-6250 has >10-fold selectivity for NTCP *in vitro* compared to other evaluated BA transporters, including organic anion-transporting protein (OATP) 1B1 and OATP1B3. ABI-6250 has high metabolic stability in human, NHP, and rat LMs (predicted clearance = 1.0–2.5 ml/min/kg) and good oral bioavailability (F = 100% in mice, rats, and NHPs), with a terminal half-life of 4 to 5 hours in rodents and 15 hours in NHPs. PK/PD studies in NHPs show dose-dependent ABI-6250 plasma exposure and increasing BA levels at low therapeutic doses, between 0.3 and 3 mg/kg, without affecting OATP1B1 and OATP1B3 (demonstrated by monitoring coproporphyrin plasma levels), indicating ABI-6250 effectively and selectively inhibits NTCP *in vivo*. ABI-6250 is well tolerated at exposures above the expected efficacious concentration when orally dosed daily for 7 consecutive days in rats and NHPs.

Conclusion: ABI-6250 is a highly potent, orally bioavailable HDV entry inhibitor with a preclinical profile supporting a once-daily oral therapy for cHDV and is expected to enter Phase 1 clinical studies by the end of 2024.

WED-378

Association of baseline characteristics and plasma ALG-001075 to HBsAg responses in HBsAg+ CHB subjects following ALG-000184 ± ETV treatment

Kha Le¹, Man-Fung Yuen², Edward J. Gane³, Kosh Agarwal⁴, Jinlin Hou⁵, Junqi Niu⁶, Yanhua Ding⁶, Xieer Liang⁵, Alina Jucov⁷, Min Wu¹, Maida Maderazo¹, Lawrence Blatt¹, Tse-I Lin¹, Matt McClure¹, Sushmita Chanda¹. ¹Aligos Therapeutics, Inc., South San Francisco, United States; ²Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, China; ³Faculty of Medicine, University of Auckland, Auckland, New Zealand; ⁴King's College Hospital, Institute of Liver Studies, London, United Kingdom; ⁵Nanfeng Hospital, Southern Medical University, Guangzhou, China; ⁶The First Hospital of Jilin University, Changchun, China; ⁷ARENIA Exploratory Medicine, Republican Clinical Hospital and Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Moldova
Email: schanda@aligos.com

Background and aims: ALG-000184 is a prodrug of ALG-001075, a potent chronic hepatitis B (CHB) capsid assembly modulator-empty that inhibits viral replication and cccDNA establishment in vitro.

Method: ALG-000184-201 is a multi-part, multi-center, double-blind, randomized, placebo-controlled study (NCT04536337). In Part 4, eligible treatment naïve or currently-not-treated HBeAg+ CHB subjects that enrolled in Cohorts 1 and 2 were randomly assigned (3:1) to receive oral daily doses of 100 and 300 mg ALG-000184, respectively or placebo in combination with entecavir (ETV) × 12 weeks followed by open-label treatment with 100 mg ALG-000184 + ETV × ≤12 weeks and 300 mg ALG-000184 + ETV × ≤96 weeks, respectively. Those enrolled in Cohort B received open-label daily doses of 300 mg ALG-000184 alone × ≤96 weeks. A total of 22 subjects (n = 4, 9, and 9 in Cohorts 1, 2 and B, respectively) with at least 24 weeks of ALG-000184 dosing were included in the analysis. Baseline participant characteristics, including age, sex, ethnicity, HBV genotype, HBsAg, HBeAg, HBcrAg and steady state plasma ALG-001075 exposures, and change from baseline of HBsAg at weeks 24, 36 and 48 were measured. Exploratory linear univariate and multiple regression models were used to determine possible associations between selected baseline variables, plasma ALG-001075 exposures and HBsAg reduction.

Results: Substantial reductions in HBV DNA/RNA and HBV antigens have been noted for ALG-000184 + ETV and ALG-000184 monotherapy. In a multiple regression model, baseline HBsAg (< or ≥4 log₁₀ IU/ml) and steady state plasma ALG-001075 exposure (AUC or C_{trough}) statistically significantly predicted change from baseline in HBsAg at week 24 (p < 0.00018, R² = 0.65). Baseline HBsAg of ≥4 log₁₀ IU/ml was a significant predictor of having a HBsAg reduction. Higher plasma ALG-001075 exposures added statistically significantly to the prediction (p < 0.01). Baseline HBcrAg (≥4 log₁₀ IU/ml) was a significant predictor of HBsAg reduction based on univariate regression analysis but did not add statistical significance to baseline HBsAg and plasma ALG-001075. Similar results were observed at weeks 36 and 48. There were no statistically significant associations found between age, sex, ethnicity, HBV genotype, baseline HBeAg or ALT and change from baseline in HBsAg. HBeAg+ CHB subjects treated with ALG-000184 had dose related decrease in HBeAg and HBcrAg irrespective of their baseline.

Conclusion: Higher baseline HBsAg (≥4 log₁₀ IU/ml) and plasma ALG-001075 levels appear to be predictors of HBsAg response to ALG-000184 treatment while HBV DNA, RNA, HBeAg and HBcrAg declines are independent of their baseline characteristics.

WED-379

Intrahepatic changes in immunologic and virologic markers during siRNA JNJ-73763989 (JNJ-3989) based treatment of chronic hepatitis B (CHB) patients: imaging mass cytometry (IMC) analyses from the INSIGHT study

Kim Thys¹, Marjolein Crabbe¹, Hans Wils¹, Hinrich Goehlmann¹, Simon Verheijden¹, Pietro Lampertico², Tarik Asselah³, Edward J. Gane⁴, Scott K. Email: kthys@its.jnj.com

Background and aims: The evaluation of patients with chronic hepatitis B (CHB) focuses primarily on the peripheral compartment due to difficulties obtaining samples directly from the liver, the site of viral infection. In the INSIGHT study, we analyzed intrahepatic changes in CHB patients under JNJ-3989 treatment.

Method: In INSIGHT, CHB patients who were hepatitis B e-antigen (HBeAg) positive and not currently treated (Group 1) or HBeAg-negative and virologically suppressed by nucleos (t)ide analogs (NA) (Group 2) received 48-weeks of siRNA JNJ-3989 + NA ± CAM-E JNJ-6379. Core liver biopsies (CLB) were collected at baseline and week 40 and assessed using Hyperion imaging mass cytometry. This method assessed non-parenchymal and liver immune cells for 30 proteins, including viral HBsAg, Ki67 as a proliferation marker, and several immune markers. All cells were classified into eight distinct phenotypes of lymphocytes/monocytes, hepatocytes, and structural cells using 11 markers: Collagen type1, Pan-keratin, cytokeratin18, CD45, CD20, CD3, CD4, CD8, CD57, CD68, and CD14. HBsAg was used to distinguish infected from non-infected hepatocytes.

Results: Nineteen baseline- and fifteen week 40 CLB samples were assessed. Differential protein abundance analysis showed higher proportions of immune cell markers in infected than non-infected hepatocytes. NKp46, an activation marker of NK cells, was significantly enriched in infected (5%) vs non-infected hepatocytes (<1%). Also, the proportion of PDL-2-positive cells was significantly higher (p = 0.003) among the infected hepatocytes. The proportion of Ki67-positive cells was higher (p = 0.022) among the non-infected than the infected hepatocytes. The proportion of HBsAg positive hepatocytes was significantly lower (p < 0.001) at week 40 compared to baseline in both cohorts, consistent with the effect of JNJ-3989. The proportion of CD8+ T-cells was significantly lower (p = 0.002) at week 40 compared to baseline in Group 1 but not in Group 2. Differential abundance analysis of proteins within the different cell types highlighted Ki67 as significantly reduced (p < 0.05) in both infected and non-infected hepatocytes at week 40 compared to baseline in Group 1. In addition, the proportion of PDL-1-positive cells among the infected hepatocytes showed a trend for an increase in both groups during treatment (p = 0.058). This effect was absent in the non-infected hepatocytes.

Conclusion: Spatial single-cell profiling of immune and viral markers in the liver from CHB patients demonstrated a decrease in the numbers of infected hepatocytes with a trend towards higher proportions of PDL-1 positive hepatocytes after 40 weeks of treatment with JNJ-3989. Although there was a lower proportion of Ki67-positive cells among the infected hepatocytes, proportions were further reduced in all hepatocytes during treatment, indicating less proliferation.

Email: wangdong@hepathera.com

Background and aims: HT-102, is an investigational monoclonal antibody, targeting the antigenic loop of hepatitis B surface antigen (HBsAg) with the potential to functions as 1) inhibition of hepatitis B

POSTER PRESENTATIONS

virus (HBV) entry into cells, 2) elimination of virions and sub-viral particles for the treatment of chronic HBV infection. This first-in-human study investigated the safety, tolerability and single-dose pharmacokinetic (PK) profile of HT-102 in Chinese healthy subjects.

Method: The randomized, double-blind, placebo-controlled, single-ascending dose phase I a study enrolled 32 healthy subjects. 8 healthy subjects per cohort were randomized (6:2 ratio) to receive a single subcutaneous (SC) dose of HT-102 (50, 150, 300, 600 mg) or placebo. Serum PK samples were collected over 24 hours (day 1), and on days 2 to days 56 across pre to post-dose period. Anti-drug antibody (ADA) was assessed on day1 (pre-dose), days 14, days 28 and days 56. Safety assessments included adverse events (AEs), clinical laboratory tests, vital signs, physical examinations and 12-lead electrocardiograms. Injection-site tolerability assessments were performed pre-dose 30 min, post-dose 30 min, 2 h, D2 and D3 for first dose and pre-dose 30 min, post-dose 30 min, 2 h for other dosage period. Safety and tolerability was assessed based on CTCAE v5.0.

Results: The results showed good safety and tolerability of HT-102 in healthy volunteers. All treatment-emergent adverse events (TEAEs) were grade 1 or 2 in HT-102 group. No SAE or TEAEs led to premature study discontinuation or death were reported in HT-102 group. The most common TEAEs (>10% subjects) included blood uric acid increased and blood fibrinogen decreased. HT-102 was absorbed after SC injection with a median T_{max} of 119.9–312.5 h, and median serum half-life ($t_{1/2}$) of 428.0–528.6 h. Following administration of 50–600 mg HT-102, the maximum concentrations (C_{max}) and area under the concentration-time curve to the time of the last quantifiable concentration (AUC_{0-t}) ranges of healthy subjects were 5373.0–64895.4 ng/ml and 3515241.8–49624629.1 h*ng/ml, respectively. HT-102 exposure including C_{max} and AUC_{0-last} increased in a dose-proportional manner and PK parameters C_{max} , AUC_{0-168h} , AUC_{0-t} , $AUC_{0-\infty}$ showed linear kinetic characteristics across single SC dose range of 50–600 mg. All samples for ADA test were negative except one sample on Day 56 from 150 mg cohort tested ADA positive (titer 3.6) with a negative result for further Nab test.

Conclusion: A single SC dose of HT-102 at 50–600 mg was safe and well tolerated with a favorable PK profile in Chinese healthy subjects. These data support further clinical development of HT-102 for HBV infection treatment.

Email: harel.dahari@gmail.com

Background and aims: Recent in vitro studies indicate a loss of hepatitis D virus (HDV) infectivity upon farnesyl transferase inhibitor treatment. We identified 2 patients in the Phase 3 D-LIVR study who had detectable HDV RNA at the end of therapy (EOT) with Isoniazid (LNF) + ritonavir for 48 weeks and became HDV RNA negative at the end of 24-week follow-up (EOFU). This observation prompted us to develop a new mathematical model for HDV that considers infectious (V_i) and non-infectious (V_{ni}) virus.

Method: 144 patients in the D-LIVR study (NCT03719313) were treated with LNF+ritonavir for 48 weeks. 4 patients had HDV target not detected (TND) at EOFU. Two of the 4 patients had HDV detected at EOT, including one who had large HDV fluctuations during therapy with an ALT flare during EOT and follow-up and one who had a biphasic HDV decline until Week 12 that was followed by a plateau (~3 log below baseline) until EOT with normal ALT levels from Week 8 until EOFU. The mathematical model assumes that in addition to LNF blocking V_i and V_{ni} production, LNF further enhanced the ratio of V_{ni} to V_i , which led to <1 infectious-virus particle in the total extracellular body fluid (~13, 500 ml) prior to EOT. Since HBsAg remained at baseline level during LNF therapy, the number of infected cells were held constant. We assume that at baseline, 99% of total virus ($V_i + V_{ni}$) is infectious and that V_i and V_{ni} have similar clearance rate constant from blood. Key parameters of the model include the production rate constants for V_i and V_{ni} , the efficacy of LNF in blocking both V_i and V_{ni} production, and a parameter that accounts for LNF increasing the efficacy of blocking V_i production, resulting in a gradual increase of V_{ni} which increases the ratio of V_{ni} to V_i during therapy.

Results: The model was able to reproduce the total HDV kinetic pattern, i.e., a biphasic viral decline that lasted ~12 weeks followed by a viral plateau until EOT. The model predicts that while V_i declined in a biphasic manner until reaching <1 infectious-virus particle in the extracellular body fluid prior to EOT, V_{ni} had a transient decline at the beginning of therapy that was followed by a V_{ni} plateau. Modeling suggests that in addition to LNF blocking V_i and V_{ni} production ($\epsilon \sim 94.4\%$), LNF further enhanced the ratio of V_{ni} to V_i , thus increasing the log (V_{ni}/V_i) from -2 to 6 by EOT, which led to <1 infectious-virus particle in the extracellular body fluid prior to EOT.

Conclusion: This new HDV model can explain why patients, despite having detectable HDV RNA by EOT, subsequently achieved negative HDV RNA status during follow-up. Further research is needed to validate the existence of V_i and V_{ni} dynamics in LNF-treated patients to be able to test and refine our theoretical efforts in understanding LNF antiviral mode of action.

Email: avaiillant@replicor.com

Background and aims: The nucleic acid polymer (NAP) REP 2139-Mg demonstrated safety and antiviral efficacy in patients with hepatitis B/D virus (HBV/HDV) coinfection. We undertook to measure changes in hepatic venous pressure gradient (HVPG) accompanying antiviral response patients with HBV/HDV cirrhosis.

Method: REP 2139-Mg (250 mg SC qW)-available through a named patient use program (NCT05683548)-was administered for 48 weeks together with pegylated interferon (pegIFN, 90 μ g SC qW) and concomitant TAF or TDF therapy in 3 HDV/HBV patients, who failed previous bulevirtide therapy. All patients had cirrhosis and clinically significant portal hypertension (CSPH) and thus, also underwent HVPG measurement at baseline (BL), at week (W)12 and W48 (end of therapy, EOT).

Results: Patient 1 (Caucasian male, 69 y.o., Child-A5, large varices, HVPG 17 mmHg) had BL HDV-RNA of 3.28 log₁₀ copies/ml and quantitative HBs antigen (qHBsAg) 1202 IU/ml. By EOT, no antiviral response nor ALT flare was observed despite switching to weekly i.v. administration of REP 2139-Mg week 20 and dose increase to 500 mg

by week 36, but qHBsAg decreased to 760 IU/ml. HVPg at W12 decreased to 14 mmHg (-18%) returned to BL with 17 mmHg (0% from BL) at EOT. Patient 2 (Caucasian female, 51 y.o., Child-A5, large varices, HVPg 14 mmHg) had BL HDV-RNA of 4.97 log₁₀ copies/ml and qHBsAg of 626 IU/ml. The patient developed an ALT flare (max. 683 U/L, max. bilirubin 6.9 mg/dL) at W8, which was also seen with previous pegIFN exposure. After pegIFN discontinuation, ALT and bilirubin steadily declined during continued REP 2139-Mg therapy. HDV-RNA was negative by week 16. The patient was switched to IV administration by week 37. By EOT, HDV-RNA remained negative, qHBsAg was at 0.5 IU/ml, and ALT was normal at 28 U/L. HVPg increased to 17 mmHg (+21%) at week 12 but returned to 14 mmHg (0% from BL) at EOT. Patient 3 (Caucasian male, 38 y.o., Child-A5, large varices, HVPg 22 mmHg) had a BL HDV-RNA of 4.52 log₁₀ copies/ml and a qHBsAg of 922 IU/ml. After an initial ALT flare (max. ALT 659 U/L, bilirubin within normal range) at W7, HDV-RNA was negative by week 27. By EOT, HDV-RNA remained negative, qHBsAg was at 0.18 IU/ml, and ALT 41 U/L. HVPg was 18 mmHg (-18%) at W12 and remained decreased to 19 mmHg (-14%) at EOT. REP 2139-Mg was well tolerated with no severe adverse events. SC injections were accompanied by local and transient grade 1 erythema and itching in patient 2. No adverse events were associated with IV infusion.

Conclusion: Weekly REP 2139-Mg in combination with TDF and low-dose pegIFN appeared safe and effective against HBV/HDV infection in patients with cirrhosis and CSPH. Potential ALT flares should be monitored closely but may reflect an immune response triggering the subsequent decrease/loss of HDV-RNA and of HBsAg-as observed in 2 out of our 3 patients. Portal hypertension may remain controlled despite ALT flares during REP 2139-Mg therapy in patients with CSPH.

WED-386

A double-blind, placebo-controlled, single-ascending dose phase I a study to evaluate the safety, tolerability, and pharmacokinetics of HT-101, an investigational small interfering ribonucleic acid targeting hepatitis B virus in Chinese healthy subjects

¹Research Ward, Beijing Friendship Hospital, Capital Medical University, Beijing, China; ²Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China; ³Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China
Email: wangdong@hepathera.com

Background and aims: HT-101 is an N-acetylgalactosamine (GalNAc)-conjugated small interfering ribonucleic acid (siRNA) targeting hepatitis B virus. Preclinical studies exhibited a promising potential for the treatment of chronic hepatitis B virus (HBV) infection. This first-in-human study investigated the safety, tolerability and single-dose pharmacokinetic profile of HT-101 in Chinese healthy subjects.

Method: The randomized, double-blind, placebo-controlled, single-ascending dose phase I a study enrolled 50 healthy subjects. Two subjects received a single subcutaneous (SC) dose of HT-101 at 25 mg, and in other six cohorts (n=8 per cohort), healthy subjects were randomized (6:2) to receive a single SC dose of HT-101 (50~800 mg) or placebo. Blood and urine samples were obtained for pharmacokinetic determination across a 48 h post-dose period. Safety assessments included adverse events (AEs), clinical laboratory tests, vital signs, physical examinations and 12-lead electrocardiograms pre- and post-dosing. Safety and tolerability was assessed based on CTCAE v5.0.

Results: The results showed good safety and tolerability of HT-101 in healthy subjects. No subjects discontinued due to any AE, no serious AE nor death were reported. The most common AEs included increased blood triglycerides, decreased lymphocyte percentage and decreased haemoglobin. HT-101 was rapidly absorbed, with consistent pharmacokinetic parameters observed for both sense strand and antisense strand characterizations. Plasma

pharmacokinetics characterized by functional antisense strand revealed a median time to peak plasma concentration (T_{max}) of 2.5~6.0 h and median plasma half-life (t_{1/2}) of 2.5~6.1 h. Following 25~800 mg SC dose, the maximum concentrations (C_{max}) and area under the concentration-time curve to the time of the last quantifiable concentration (AUC_{0-t}) were 75.3~5120.0 ng/ml and 553~57100 h*ng/ml, respectively. HT-101 exposure increased in a slightly supra-proportional to dose manner following 25~800 mg SC dose, suggesting that at liver target site there might be a saturation mechanism with the dose increasing. After a single SC dose, the average renal clearance rate (CLR) of HT-101 ranged from 4.6 to 6.7 L/h, with fractional excretion (Fe) at 13.1~41.9% and accumulated excretion (Ae) at 3.6~331.0 mg. In 25~200 mg cohorts, Fe was 13~17%, which increased to 30~40% within 400~800 mg cohorts. This shift also suggested saturation of the liver absorption, leading to enhanced urinary excretion. Notably, no metabolites were detected in plasma or urine, aside from the original drug HT-101. The concentration-QTc analysis indicated that risk of prolonged QTc interval was not observed.

Conclusion: A single SC dose of HT-101 at 25~800 mg was safe and well tolerated in Chinese healthy subjects. These data support further clinical development of HT-101 for HBV infection treatment.

WED-387

Study on the role of dendritic cells in CHB patients treated with intermittent Interferon therapy

Liu Yang¹, Tingting Jiang², Shiyu Wang², Ziyu Zhang², Xinxin Li², Yao Xie³, Minghui Li⁴.
¹Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China; ²Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China; ³Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Department of Hepatology Division 2, Peking University Ditan Teaching Hospital, Beijing, China; ⁴Department of Hepatology Division 2, Peking University Ditan Teaching Hospital, Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing, China
Email: wuhm2000@sina.com

Background and aims: To investigate the relationship between the frequency of DCs subsets and the expression of surface co-stimulatory molecules and chemokine receptors in patients with CHB and the plateau of slow decline of HBsAg and the clinical efficacy during IFN intermittent therapy.

Method: CHB patients were divided into IFN initial treatment group (patients with natural history of CHB without any antiviral treatment before, and were given IFN antiviral treatment after admission, namely NH group, NAs treated group (NA group) and IFN treated plateau arriving group (P group). After perfecting the baseline related examination, the patients in the NH group were given IFN alone or in combination with NAs antiviral therapy; patients in the P group were retreated with IFN after 12~24 W of IFN intermission. For patients in the NH group, at baseline before IFN treatment, at 4 W and 12~24 W after IFN treatment; patients in NA group at baseline; patients in P group at baseline when IFN was stopped, 12~24 W of IFN intermission and 12~24 W of IFN retreatment, the viral, serological, biochemical and DC related indicators were collected.

Results: 49 patients in NH group, 47 patients in NA group and 47 patients in the P group were included. At baseline, the percentage of CD141 and CD1c double negative myeloid dendritic cells (DN mDC) subset, the percentage of CD86⁺ cells in DN mDC and the CD86 MFI of CD86⁺ DN mDC, the percentage of CX3CR1⁺ cells in DN mDC and the CX3CR1 MFI of CX3CR1⁺ DN mDC in the P group were significantly lower than those in the NA group and NH group. 35 patients in P group were followed up for 12~24 W of IFN intermission. The percentage of DN mDC increased significantly, and the percentage of CD86⁺ cells in DN mDC, CD86 MFI of CD86⁺ DN mDC, CX3CR1⁺ cells in DN mDC and CX3CR1 MFI of CX3CR1⁺ DN mDC increased significantly; Twelve patients in the P group were followed up until

POSTER PRESENTATIONS

12–24 W of IFN retreatment, and the data of three follow-up points were obtained. It was found that the proportion of DN mDC increased significantly, and the percentage of CD86⁺ cells in DN mDC, CD86 MFI of CD86⁺ DN mDC, CX3CR1⁺ cells in DN mDC and CX3CR1 MFI of CX3CR1⁺ DN mDC all showed a trend of increasing first and then decreasing. 11 patients in the NH group were followed up until IFN treatment 12–24 W. It was found that the percentage of DN mDC decreased significantly after 4 W and 12–24 W use of IFN; CD86 MFI of CD86⁺ DN mDC after 4 W and 12–24 W use of IFN were significantly lower than those in baseline; the percentage of CX3CR1⁺ cells in DN mDC after 4 W and 12–24 W use of IFN decreased significantly compared with baseline; The CX3CR1 MFI of CX3CR1⁺ DN mDC after 12–24 W use of IFN was significantly lower than that of baseline.

Conclusion: IFN treatment significantly decreased the percentage of DN mDC subsets, and the percentage of CD86⁺ and CX3CR1⁺ cells in DN mDC and their CD86 and CX3CR1 MFI. In the P group the above indexes recovered to some extent after 12–24 W of IFN intermission.

WED-388

Safety, tolerability, and hepatitis B surface antigen reduction of HT-101 in chronic hepatitis B patients: preliminary results from a phase I b study

Dong Wang¹, Shanzhong Zhang², Yanqin Ma², Lijuan Ding², Zhipeng Zhang², Hong Ma², Jidong Jia³. ¹Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China; ²Suzhou Hepa Thera Biopharmaceutical Co. Ltd., Shanghai, China; ³Liver Research Center, Beijing Friendship Hospital, Beijing, China
Email: wangdong@hepathera.com

Background and aims: HT-101 is an N-acetylgalactosamine (GalNAc)-conjugated small interfering ribonucleic acid (siRNA) targeting hepatitis B virus. Preclinical studies exhibited a promising potential for the treatment of chronic hepatitis B virus (HBV) infection. Here we reported preliminary data from an ongoing study evaluating the safety, tolerability, and antiviral activity of HT-101 in chronic HBV infection participants with nucleos (t)ide reverse transcriptase inhibitor (NRTI) treatment.

Method: This was a randomized, double-blind, placebo-controlled, phase Ib, multiple ascending doses study of HT-101 administered via subcutaneous (SC) injection to chronic hepatitis B patients who received continuous NRTI therapy for ≥6 months. Participants with non-cirrhosis (<F3) were restricted with HBsAg <5,000 IU/ml at screening. Participants received two subcutaneous HT-101 injections, 4 weeks apart, of 50, 100, 200 or 400 mg. At each dose level, eight participants were randomly assigned to HT-101 or placebo (6:2 ratio). Follow-up was carried out for 24 weeks post first dose. The protocol conformed to the Declaration of Helsinki guidelines and was approved by appropriate institutional review committee (s). Written informed consent was obtained prior to study procedures.

Results: Thirty-three participants with chronic hepatitis B (including 1 participant prematurely discontinued) were randomly assigned to receive two doses of HT-101 (50, 100, 200 or 400 mg) or placebo, given 4 weeks apart. So far, all patients showed good safety and tolerability. No subjects discontinued due to an adverse event (AE), no serious adverse events (SAE) nor death were reported. The follow-up visit is still ongoing and the data has not been un-blinded. According to preliminary pharmacodynamics data available in 50 mg and 100 mg cohorts: Demographic and baseline characteristics were generally well balanced across treatment groups (baseline HBsAg: 2.85 ± 0.37 log₁₀ IU/ml for 50 mg group; 2.94 ± 0.37 log₁₀ IU/ml for 100 mg group). The mean log reduction in HBsAg level in 50 mg and 100 mg cohort plotted against time was depicted in figure (4 participants without HBsAg reduction exclusive). Higher doses of HT-101 were associated with greater HBsAg reduction. In 100 mg HT-101 group, the mean reduction of HBsAg at Week 12 achieved (2.28 ± 0.64 log₁₀ IU/ml) and in 50 mg group, the mean reduction of HBsAg at Week 16 achieved (1.50 ± 0.51 log₁₀ IU/ml).

Conclusion: Two monthly doses of HT-101 administered SC were well safe and tolerated in Chinese patients with chronic HBV infection. Dose-dependent significant reductions from baseline in serum HBsAg levels were achieved through up to 16 weeks post last dose. Higher doses of HT-101 will be evaluated in subsequent cohort. These data support the continued development of HT-101 for treatment of chronic HBV infection.

WED-389

Pharmacokinetics and safety of the monoclonal antibody tobevibart (VIR-3434) administered as monotherapy or in combination with the small interfering RNA elebsiran (VIR-2218) in cirrhotic participants with mild hepatic impairment

Li Wang¹, Sneha Gupta¹, Michael A. Chattergoon¹, Asma El-zailik¹, Cheng Huang¹, George Hristopoulos¹, Maribel Reyes¹. ¹Vir Biotechnology, Inc., San Francisco, United States
Email: liwang@vir.bio

Background and aims: Tobeivart (VIR-3434) is a human immunoglobulin G1 (IgG1) monoclonal antibody (mAb) that binds to the antigenic loop present in all forms of hepatitis B surface antigen (HBsAg). Elebsiran (VIR-2218) is a N-acetylgalactosamine (GalNAc)-conjugated, double-stranded RNA interference (RNAi) therapeutic that targets the X region of the hepatitis B virus (HBV) genome that is common to all HBV viral RNA transcripts. Here, we report the pharmacokinetics (PK) and safety of tobeivart administered as monotherapy or in combination with elebsiran in cirrhotic participants who have mild hepatic impairment with a Child-Pugh-Turcotte Class-A (CPT-A) score, and in matched healthy volunteers (HV).

Method: VIR-2218-V107 (NCT05484206) is a Phase 1, open-label, single-dose parallel-group study. CPT-A and HV participants were demographically matched. Participants received a single subcutaneous (SC) dose of tobeivart 300 mg or tobeivart 300 mg + elebsiran 200 mg. Blood samples were collected up to 18 weeks post-dose to measure the concentrations of tobeivart, elebsiran and its major metabolite. Safety and tolerability were monitored throughout the study.

Results: Eight cirrhotic CPT-A participants and 8 HV participants (matched by demographics) were enrolled in each cohort (tobeivart monotherapy and tobeivart/elebsiran combination therapy). Tobeivart PK exposure was comparable in CPT-A and HV participants. Preliminary geometric mean ratios (GMR) of tobeivart C_{max} and AUC_{inf} in CPT-A to HV participants were 0.96 (90% CI: 0.64–1.42) and 0.94 (90% CI: 0.72–1.23) in tobeivart monotherapy, and 1.06 (90% CI: 0.71–1.59) and 1.01 (90% CI: 0.73–1.40) in tobeivart/elebsiran combination therapy, respectively. Tobeivart PK was similar in mono and combo therapy in both CPT-A and HV participants, indicating no PK drug-drug interaction (DDI) between tobeivart and elebsiran. Exposure of elebsiran was also comparable in CPT-A and HV participants. Preliminary GMR of C_{max} and AUC_{inf} in CPT-A to HV was 0.94 (90% CI: 0.53–1.68) and 1.54 (90% CI: 1.15–2.05), respectively. Tobeivart and elebsiran were generally well tolerated in cirrhotic CPT-A participants. One SAE of asthma exacerbation was reported in a CPT-A participant who received tobeivart 300 mg monotherapy. The participant has a prior history of asthma flares requiring emergency department management and the SAE was considered unrelated to tobeivart.

Conclusion: Tobeivart and elebsiran exposures were comparable in CPT-A and HV participants. A single dose of tobeivart 300 mg mono and tobeivart 300 mg + elebsiran 200 mg combo therapy was well tolerated in CPT-A participants and no drug related SAE was observed. The data supports continued evaluation of the tobeivart 300 mg monotherapy and tobeivart 300 mg + elebsiran 200 mg combination therapy in patients with HBV and HDV infection with CPT-A hepatic impairment.

Evaluation of liver fibrosis in patients with advanced chronic liver disease due to hcv after 6 years of sustained viral response. study with paired biopsies at 3 and 6 years

Lidia Canillas^{1,2,3}, Dolores Naranjo⁴, Teresa Broquetas^{1,2}, Zoe Mariño^{5,6,7,8}, Xavier Forns^{5,6,7,8}, Jose A. Carrión^{1,2,3,9}. ¹Liver Section, Gastroenterology Department, Hospital del Mar, Barcelona, Spain; ²Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; ³Department of Medicine and Life Sciences, Universitat Pompeu Fabra, Barcelona, Spain; ⁴Gastrointestinal and Hepatobiliary Pathology Section, Department of Pathology, Hospital del Mar, Barcelona, Spain; ⁵Liver Unit, Hospital Clínic, Barcelona, Spain; ⁶Institut D'investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Barcelona, Spain; ⁷Centros de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Madrid, Spain; ⁸Department of Medicine, Medicine and Life Sciences School, Universitat de Barcelona, Barcelona, Spain; ⁹Department of Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain
Email: jcarrion@psmar.cat

Background and aims: More than half of hepatitis C virus (HCV) infected patients with advanced chronic liver disease (ACLD) (transient elastography, TE>10 kPa) treated with direct-acting antivirals (DAAs) had cirrhosis (METAVIR = F4) after 3 years of sustained viral response (SVR) (Broquetas et al. Liver Int. 2021 Nov;41 (11):2733–2746). We aimed to evaluate the fibrosis stage in HCV-infected patients with ACLD after 6 years of SVR and to assess the diagnostic reliability of TE to identify cirrhosis and fibrosis regression. **Method:** Prospective and multicentric study in patients with ACLD due to HCV that achieved SVR with DAAs. Fibrosis stage was assessed with liver biopsy after 3 (LB3) and 6 (LB6) years of SVR according to the METAVIR scale. Fibrosis progression was defined as METAVIR increase, regression as METAVIR decrease, and stability as METAVIR without change. The TE's diagnostic reliability (c statistic) was evaluated to identify cirrhosis (F4) and fibrosis regression.

Results: We included 76 patients. We excluded 26 (33%) patients from the analysis for different reasons (death, comorbidities, anticoagulant treatment, etc.). Thus, we analyzed data of 50 (67%) patients with LB6, and 32 (64%) of them had paired biopsies (LB3 and LB6). Among patients with LB6 (N = 50), the median (IQR) age was 54 (49–60) and 72% were men. Before treatment, the median (IQR) of TE was 16.9 (13.1–21.8) kPa. Hence, 29 (57%) patients had TE >15 kPa, and 22 (43%) had TE 10–15 kPa. After 6 years of SVR, the median (IQR) of TE was 9.6 (7.5–13.3) kPa. The LB6 showed fibrosis stage (METAVIR) F2 in 13 (26%), F3 in 21 (43%), and F4 in 15 (31%) patients. Among patients with paired biopsies (LB3 and LB6) (n = 32), fibrosis regression was observed in 6 (19%) patients, progression in 11 (34%), and stability in 15 (47%) patients. Patients with fibrosis progression compared to those with regression or stability of fibrosis had more frequently diabetes (46% vs 29%), obesity (50% vs 29%), hypertension (73% vs 52%), and alcohol consumption of >20–30 g/day (22% vs 5%) without reaching statistical significance (all p = ns). The discrimination capacity (c-statistic) of TE to identify patients with cirrhosis after 6 years of SVR was 0.761 and to identify patients with fibrosis regression was 0.423.

Conclusion: Persistent cirrhosis is frequent, even 6 years after SVR, in patients with advanced chronic liver disease. The diagnostic reliability of transient elastography is not enough to identify patients with persistent cirrhosis after SVR. Fibrosis regression after SVR is slow in patients with advanced chronic liver disease requiring invasive techniques for its recognition.

THU-378

Prediction of outcomes in patients with HCV compensated liver cirrhosis after SVR: results from 5-years of follow-up

Filomena Morisco¹, Alessandro Federico², Massimo Marignani³, Flavia L Lombardo⁴, Valentina Cossiga¹, Luisa Ranieri¹, Mario Romeo², Marina Cipullo², Paola Begini³, Federico Gioli³, Tommaso Stroffolini⁵. ¹Department of Clinical Medicine and Surgery, Departmental Program "Diseases of the liver and biliary system", University of Naples "Federico II", Naples, Italy, Naples, Italy; ²Hepato-Gastroenterology Unit, University of Campania Luigi Vanvitelli, Naples, Italy, Naples, Italy; ³Department of Digestive and Liver Disease, S. Andrea University Hospital, Rome, Italy, Rome, Italy; ⁴National Center for Disease Prevention and Health Promotion, Italian National Institute of Health, 00161 Rome, Italy, Rome, Italy; ⁵Department of Tropical and Infectious Diseases, Policlinico Umberto I, Rome, Italy, Rome, Italy
Email: filomena.morisco@unina.it

Background and aims: In cirrhotic patients with HCV infection, the clinical challenge for physicians after achieving sustained virological response (SVR) is to accurately identify the subset of patients at-risk of developing liver-related event (LRE). The aims of our study are to: 1) evaluate incidence of and risk factors for LRE in a cohort of advanced chronic liver disease (ACLD) patients treated with DAA; 2) to evaluate the dynamic changes of liver stiffness in a subgroup of patients with favorable outcomes in 5 years of follow-up.

Method: A prospective multicenter study was conducted in 3 Italian centers. Consecutive patients with HCV-related ACLD starting DAA therapy between September 2014 and June 2018 were enrolled. Patients were followed for a mean period of 4.6 years after achieving SVR12 with regular biannual clinical, laboratoristic and instrumental follow-up. The at-risk period for each subject was defined by the time from the SVR12 until the end of follow-up or the onset of event. Cumulative and separate analysis were made according to the development of LRE.

Results: A total of 575 patients with ACLD achieving SVR12 were followed-up for 5 years. The male/female ratio was 1.1 and the mean age was 64.1 ± 12 years. Nearly all subjects (94.4%) belonged to the Child- Pugh A stage. The mean liver stiffness (LSM) at baseline was 19.2 kPa. Overall, 98 (17%) patients developed any type of events and the mortality rate was of 8.8% (3% for liver-related cause). The HCC was the most frequent LRE (7.1%), followed by ascites (5%). The incidence rate was 1.6 (95%CI 1.2–2.2) per 100 person/year (p/y) for both HCC and liver decompensation. Among pre-treatment variables, LSM≥20 kPa (HR 13.5; 95% CI 5.2–35.3) was the only independent predictor of liver decompensation, while liver stiffness≥20 kPa (HR 9.2; 95% CI 4.0–21.3) and male sex (HR 3.6 95% CI 1.6–8.0) both were independent predictors of HCC development. Overall, 477 subjects did not experience LRE during the follow-up and, among these, paired LSM were available for 341 (71.5%) subjects. In this subgroup, the mean LSM, at SVR12, was 16.9 ± 4.2 kPa and decreased to 13.0 ± 4.0 kPa at the end of follow-up (T60). Overall, any LSM reduction was observed in 314 (92.1%) subjects with a mean reduction of 4.4 kPa. Among these 314 subjects, half of them showed a decrease of LSM ≥20%.

Conclusion: This study shows the relevance of baseline LSM as a tool to stratify patients at risk of developing LRE. The dynamic changes over time of LSM require a continuous long term monitoring of this parameter to update changes in fibrosis degree of subjects after SVR.

Artificial intelligence model for predicting liver-related events in non-cirrhotic patients after successful treatment by direct-acting antivirals for chronic hepatitis C

Huapeng Lin^{1,2}, Jimmy Che-To Lai², Hye Won Lee³, Terry Cheuk-Fung Yip², Sang Hoon Ahn³, Grace Lai-Hung Wong², Xiangjun Meng¹, Vincent Wai-Sun Wong², Victor de Lédighen⁴, Seung Up Kim³. ¹Shanghai Jiao Tong University, Shanghai, China; ²The Chinese University of Hong Kong, Hong Kong, Hong Kong; ³Yonsei University, Seoul, Korea, Rep. of South; ⁴Bordeaux University, Bordeaux, France
Email: linhuapeng5@163.com

Background and aims: Current guidelines recommend ultrasound screening every 6 months after sustained virologic response (SVR) in patients with chronic hepatitis C (HCV)-related cirrhosis. Identifying non-cirrhotic patients at higher risk of developing liver-related events (LREs) who could benefit from surveillance programs following HCV eradication are rarely explored. We aimed to develop and validate a machine learning-based model for LREs prediction and risk stratification in non-cirrhotic HCV patients after SVR.

Method: Random Survival Forest model was trained for prediction of LREs in 913 non-cirrhotic HCV patients after SVR in Korea and further tested in a combined cohort from Hong Kong and France (N = 1264, liver stiffness measurement [LSM] <15 kPa and no biopsy diagnosed cirrhosis). Model performance was assessed according to Harrell's C-index and time-dependent receiver operating characteristic (ROC) curve.

Results: We developed the AI-Safe score with LSM, age, sex and other six biochemistry tests. The incidence of LREs and hepatocellular carcinoma (HCC) in the validation cohort were 4.6 and 3.1 per 1000 patient-years, respectively. The C-index of the AI-Safe score in validation cohort was 0.86 (95% confidence interval [CI], 0.82–0.90). The area under ROC curves of the AI-Safe score for LREs in 3 and 5 years were 0.88 (95%CI 0.84–0.92) and 0.79 (95%CI 0.71–0.87) respectively. The C-index of the AI-Safe score for HCC in the validation cohort was 0.87 (95%CI 0.81–0.92). The AUROCs for 3-year and 5-year HCC in the validation cohort were 0.88 (95%CI 0.84–0.93) and 0.82 (95%CI 0.75–0.90). The AI-Safe score had a consistently good performance in patients with LSM <10 or 8 kPa for the predictions of LREs and also HCC. The performance of the AI-Safe score was significantly better than FIB-4, APRI and a Cox regression-based model for the prediction of LREs. Compared with existing HCC risk scores for HCV SVR patients, we could still observe a significantly better performance for AI-Safe score in the predicting of HCC. Using the cutoff of 0.08, the 5-year LREs reached 6.2% in the high-risk group but only 0.6% in the low-risk group. The 5-year HCC rate was 3.5% in the high-risk group, and 0.2% in the low-risk group.

Conclusion: The AI-Safe score is a useful machine learning-based tool to identify non-cirrhotic patients at higher risk of developing LREs.

THU-380-YI

Individualized intervals for streamlined directly observed therapy in PWIDs—a unique approach to continue HCV microelimination throughout the COVID19 pandemic

Caroline Schwarz^{1,2}, Angelika Schütz³, David Bauer^{1,2}, Enisa Gutic², Thomas Reiberger¹, Hans Haltmayer³, Michael Gschwantler^{2,4}. ¹Medical University of Vienna, Vienna, Austria; ²Klinik Ottakring, Vienna, Austria; ³Suchtthilfe Wien gGmbH, Vienna, Austria; ⁴Sigmund Freud University, Vienna, Austria
Email: michael.gschwantler@gesundheitsverbund.at

Background and aims: Direct-acting antivirals (DAA) administered via directly observed therapy (DOT) are highly effective for treating HCV in people who inject drugs (PWIDs) on opioid agonist therapy (OAT). Our traditional concept of DOT relied on DAA prescription via a low-threshold facility (LTF) and supervised administration alongside OAT at a pharmacy or LTF. In PWIDs with good adherence, intervals of

DOT distribution may be extended from daily to once weekly, however, the impact of these adjustments on sustained virologic response (SVR) rates remains unknown. While most HCV elimination efforts were interrupted through the COVID19 pandemic, we present an individualized approach for DOT HCV DAA treatment in PWIDs which was successfully maintained throughout the pandemic.

Method: This study compared DOT distribution intervals, SVR rates, and socioeconomic characteristics between two cohorts of PWIDs on OAT. The first cohort consisted of 239 PWIDs on OAT who initiated DOT with DAA between March 16, 2020, and May 2, 2023, defined as the 'COVID period'. The second cohort included 441 PWIDs starting DOT between September 26, 2014, and March 12, 2020, identified as the 'pre-COVID period'.

Results: Pre-COVID, daily DOT was the most frequent approach used in 348 (78.9%) PWIDs, compared to 19 (4.3%) and 74 (16.8%) PWIDs with 2–3 times/week and once weekly OAT/DAA dispensation, respectively. During COVID daily OAT/DAA schedules were observed in only 75 (31.4%) PWIDs, while 60 (25.1%) and 104 (43.5%) were extended to 2–3 times/week and once weekly intervals, respectively (p < 0.001). SVR rates remained high and comparable between groups (167/168 [99.4%] COVID vs. 402/405 [99.3%] pre-COVID according to modified intention-to-treat analysis; p = 0.849), with no significant difference in missed visits (59 [0.8%] COVID vs. 84 [0.4%] pre-COVID; p = 0.239). However, loss of follow-up post-therapy was more frequent in the COVID period (28.5% vs. 7.5% pre-COVID; p < 0.001). Socioeconomic status was equal or even lower during COVID (unemployment: 83.7% vs. 67.3%, p = 0.967; homelessness: 38.5% vs. 35.1%, p = 0.227; habitual alcohol consumption: 29.3% vs. 10.7%, p < 0.001; ongoing intravenous drug use: 64.0% vs. 57.8%, p = 0.616). Importantly, no treatment interruptions or COVID19-related deaths were observed.

Conclusion: The traditional "daily" DOT concept targeted adherence issues in PWIDs related to ongoing substance use, psychiatric comorbidities, and low socioeconomic status. Importantly, our novel "relaxed interval" DOT concept, with individualized, extended OAT/DAA schedules, yielded similar SVR rates. Hence, the effectiveness of DOT hinges on more streamlined linkage to HCV care and simplified DAA access through a single visit at an LTF rather than strict daily surveillance.

Email: monica.pons@vhir.org

Background and aims: In patients with hepatitis C (HCV) compensated advanced chronic liver disease (cACLD) cured with oral antivirals, follow-up (FU) liver stiffness measurement (LSM) performed after end of treatment (EOT) helps to stratify the risk of decompensation. However, information regarding prognostic performance of repeated LSM after EOT is still lacking. We aimed to evaluate the risk of liver related events (LRE) using repeated LSM after EOT and explore factors associated with LSM impairment.

Method: We retrospectively analyzed a multicentric European cohort including HCV-cACLD patients cured with oral antivirals with repeated LSM after EOT. We used 3 time-point LSM: after EOT (B-LSM), between 12 months to 36 months after EOT (LSM1) and after 54 months (LSM2). LSM impairment was defined as $\geq 20\%$ increase with respect to B-LSM with a final LSM ≥ 10 kPa. The cumulative incidence of LRE was compared between groups. LRE included decompensation events and hepatocellular carcinoma.

Results: 1052 patients with B-LSM were included. In 815 patients LSM1 was performed and in 646 LSM2 was available (in 466 all three LSM were available). During a median follow-up of 6.3 years, 80 patients developed LRE. 68 LRE occurred after LSM1 (with 23 of LRE occurring after LSM2). In 63 patients (7.7%), LSM1 worsened (increase $\geq 20\%$ with LSM1 ≥ 10 kPa) during FU vs 752 patients. Patients with LSM1 impairment had lower baseline mean platelet count ($140 \times 10^9/L$ vs $166 \times 10^9/L$, $p < 0.001$), higher bilirubin levels (0.8 mg/dL vs 0.7 mg/dL, $p = 0.016$) and higher GGT levels (45 IU/L vs 36 IU/L, $p = 0.056$) compared to patients without LSM1 impairment. No significant difference was found in metabolic risk factors neither in alcohol consumption between both groups. The incidence rate of LRE in patients with LSM1 impairment was 3.9/1000 patient-years compared to 1.9/1000 patient-years ($p = 0.024$). The risk of LRE at 5-year-FU was 20% in the LSM1 impairment group vs 11.6% in the other group ($p = 0.079$). Due to short FU after LSM2 (median 14 months), incidence of LRE related to LSM impairment was not explored.

Conclusion: In HCV-cACLD patients cured with oral antivirals, impairment in LSM during FU is not frequent but associated with a double risk of presenting LRE. Those patients in whom LSM worsens

during FU have a more advanced liver disease. In this cohort, metabolic risk factors did not associate with LSM impairment.

THU-382

Lead-in cohort results from a phase 2 study of a novel 8-week combination regimen of Bepirovir and Ruzasvir in patients with chronic hepatitis C virus infection

Email: alina.jucov@arensia-em.com

Background and aims: Bepirovir (BEM) and ruzasvir (RZR) are potent, pan-genotypic inhibitors of the HCV NS5B polymerase and the NS5A protein, respectively. In previous studies, the combination of BEM and daclatasvir ($n = 10$), and uprifosbuvir and RZR ($n > 400$), were safe, well-tolerated, and each combination achieved high sustained virologic response (SVR) rates in HCV-infected patients. BEM+RZR exhibited synergistic anti-HCV activity *in vitro* with no pharmacokinetic (PK) drug-drug interaction in healthy subjects, prompting evaluation of this novel combination in a phase 2 open-label study assessing efficacy and safety of BEM+RZR administered for 8 weeks in 280 HCV-infected patients (NCT05904470).

Method: In this single arm study, a lead-in cohort ($n = 60$) of treatment-naïve, non-cirrhotic patients with chronic HCV (any genotype) received 550 mg BEM once daily (QD) + 180 mg RZR QD for 8 weeks. Objectives of this preliminary analysis included assessment of safety (reported adverse events [AEs], laboratory abnormalities, serial electrocardiograms [ECGs]) and efficacy (achievement of SVR4). An SVR4 rate of $\geq 90\%$ in the lead-in cohort was needed to proceed with further enrollment. Plasma HCV RNA was evaluated using the Roche cobas[®] HCV quantitative nucleic acid test for use on the cobas[®] 6800/8800 systems, with a lower limit of quantitation (LLOQ) of 15 IU/ml.

Results: The 60 lead-in patients were infected with GT1 ($n = 45$), GT2 ($n = 2$) and GT3 ($n = 13$), and 17% had F3 fibrosis. 57% were male, 95% were Caucasian, with a median age of 47 (range 25–79) years. All patients completed the 8-week treatment period with no premature treatment discontinuations or drug-related serious AEs. AEs were mostly mild; no clinically significant laboratory or ECG abnormalities were observed. Viral load decreased rapidly after treatment initiation, with 90% of patients achieving below LLOQ by week 4 (residual viral loads of the remaining patients were near LLOQ ranging from 16 to 31 IU/ml) and 100% achieving below LLOQ by end of treatment. At the time of this analysis, 58 subjects reached the SVR4 timepoint. Of these, 57 subjects (98%) achieved SVR4.

Conclusion: BEM+RZR for 8 weeks was well tolerated in HCV-infected patients. A high rate of SVR4 (98%) was documented in this preliminary analysis. All patients will continue to be followed to SVR12. Based on these results, the study will continue to enroll an additional 220 patients, including those with compensated cirrhosis.

Predictive performance of HCC risk scores in chronic hepatitis C patients with advanced fibrosis after achieving SVR: real-world experience from a tertiary UK centre

Riham Soliman¹, Saima Ajaz¹, James Lok¹, Mercy Karoney¹, Evangelos Chalatsis¹, Ivana Carey¹, Mary D Cannon¹, Kathryn Oakes², Teresa Bowyer¹, Kosh Agarwal¹, Maria Guerra Veloz¹. ¹Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom; ²Institute of Liver Studies, King's College Hospital NHS Foundation Trust, London, United Kingdom
Email: riham.soliman@nhs.net

Background and aims: Current guidelines recommend biannual hepatocellular carcinoma (HCC) surveillance in patients with chronic hepatitis C (CHC) infection and advanced liver fibrosis. However, this 'one-size-fits-all' strategy places a huge burden on healthcare systems and regression of fibrosis may occur with disease-modifying treatments. Our aim is to compare the discriminative ability of risk prediction scores for HCC development in patients with CHC who have achieved sustained virological response (SVR).

Method: In this retrospective single centre study we compared the predictive performance of the aMAP, THRI and GES scores in a cohort of patients with treated HCV infection (F3–F4) and achieved SVR with direct acting antivirals (DAAs) between 2014 and 2020. Data was collected until HCC occurrence, death or last follow-up visit. Cumulative incidences were calculated using the Kaplan-Meier method and compared using the log-rank test. The performance of each model was assessed further using Harrell's c statistics.

Results: 508 patients were included in the analysis, 70% males with a median age of 58.0 years. The majority (61.4%) were cirrhotic. By applying the GES score, 264 (52.0%), 174 (36.4%), and 70 (13.8%) of the patients were considered at low, intermediate, and high risk for HCC. Cumulative HCC incidence in the three categories were as follows: low-risk cohort (defined as GES score ≤ 6 , cumulative incidence 1.20%, 95% CI 0.65–2.04), intermediate-risk cohort (defined as score > 6 and ≤ 7.5 , incidence 2.26% CI 1.34–3.59), and high-risk cohort (scores > 7.5 , incidence 5.86%, 95% CI 3.47–9.31). For the aMAP score, 41 (8.1%), 204 (40.2%), and 263 (51.8%) of the studied patients were at low, intermediate, and high risk for HCC. Cumulative HCC incidence was 0.73% (95% CI 0.04–3.60) in their low-risk group, 0.65% (95% CI 0.24–1.43) in their intermediate-risk group, and 3.56% (95% CI 2.56–4.84) in their high-risk group. For the THRI score, 105 (20.7%), 352 (69.3%), and 15 (10.0%) of the studied patients were at low, intermediate, and high risk for HCC; cumulative incidences were 0.79% (95% CI 0.20–2.16), 2.05% (95% CI 1.40–2.91) and 6.31% (95% CI 3.42–10.73), respectively. The Harrell's c-statistic for the three scores were 0.646 (GES), 0.6723 (aMAP) and 0.6314 (THRI).

Conclusion: All three scores effectively stratified our patient cohort into low, intermediate, and high-risk groups. Screening can be safely avoided in low risk, potentially improving the cost-effectiveness of our HCC surveillance programmes.

THU-386-YI

Renin-angiotensin inhibitor intake is associated with improved survival in patients with chronic hepatitis C viral infection following SVR-data from the german hepatitis C-registry (DHC-R)

Tammo Lambert Tergast¹, Marie Griemsmann¹, Leyla Valiyeva¹, Peter Buggisch², Stefan Mauss³, Hartwig Klinker⁴, Klaus H.W. Email: tergest.tammo@mh-hannover.de

Background and aims: The role of renin-angiotensin inhibitors (RAS-Inhibitors) on the clinical course of patients with chronic liver disease remains unclear. Antifibrotic effects have been described in animal models and it has been hypothesized that RAS-Inhibitor intake could exert positive effects on the natural history of liver disease, potentially leading to lower rates of hepatocellular carcinoma (HCC), hepatic decompensation (HD) and improved survival. However, clinical data to support this are lacking. This study investigated the impact of RAS-Inhibitor intake on the clinical course of patients with chronic hepatitis C (HCV) in the well-established German Hepatitis C-Registry (DHC-R).

Method: Overall, 10703 patients were included in this study. Patients with malignancies, without sustained virological response (SVR), HIV or history of organ transplantation were excluded. Study end points were mortality, incidence of hepatic decompensation and incidence of HCC, respectively. Survival analysis was conducted via multi-variable Cox-regression, adjusting for important confounding factors such as presence of arterial hypertension, type 2 diabetes mellitus, chronic kidney disease, sex or age.

Results: RAS-Inhibitor intake was present in 2207 (21%) patients. In total, 128 events of hepatic decompensation, 130 deaths and 82 HCCs were documented during follow-up of 18783 patient years. Presence of type 2 diabetes mellitus, presence of dyslipidemia, arterial hypertension, chronic kidney disease or coronary artery disease was significantly more frequent in patients with RAS-Inhibitor intake (18% vs. 5%, $P < 0.001$, 6% vs. 1%, $P < 0.001$, 76% vs. 9%, $P < 0.001$, 6% vs. 1%, $P < 0.001$ and 9% vs. 1%, $P < 0.001$, respectively). Intake of RAS-Inhibitors was not associated with a lower incidence of hepatic decompensation (HR: 0.99, 95%CI: 0.65–1.53, $P = 0.99$) or hepatocellular carcinoma (HR: 0.77, 95%CI: 0.46–1.32, $P = 0.34$). However and importantly, RAS-inhibitor intake was independently associated with improved survival (HR: 0.54, 95%CI 0.33–0.87, $P = 0.01$) irrespective of the higher frequency of metabolic comorbidities.

Conclusion: Although the incidences of HCC or hepatic decompensation is unaffected, the intake of RAS inhibitors was associated with a reduced mortality in patients with HCV following SVR.

THU-387

Safety and efficacy of two pangenotypic direct acting antivirals (sofosbuvir/velpatasvir and glecaprevir/pibrentasvir) for the treatment of hepatitis C in children

Maria Pokorska-Śpiewak¹, Ewa Talarek², Anna Dobrzeńska³, Małgorzata Aniszewska², Magdalena Pluta², Magdalena Marczyńska². ¹Medical University of Warsaw, Regional Hospital of Infectious Diseases, Warsaw, Poland; ²Medical University of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland; ³Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland
Email: maria.pokorska-spiewak@wum.edu.pl

Background and aims: The aim of this study was to analyze and compare safety and efficacy of two pangenotypic regimens (sofosbuvir/velpatasvir, SOF/VEL and glecaprevir/pibrentasvir, GLE/PIB) used for treatment of chronic hepatitis C (CHC) in children.

Method: In this single-center study we compared outcomes of CHC treatment in two groups of children: 50 participants aged 6–18 years treated with SOF/VEL in PANDAA-PED Project, and 41 patients aged 5 to 18 years treated with GLE/PIB in POLAC Project. We included all children who had been treated since January 2022, whose evaluation of sustained viral response at 12-week posttreatment (SVR12) was performed until December 31, 2023. In all cases, fixed drug doses adjusted to the patients' weight were used.

Results: Both studied groups (SOF/VEL vs. GLE/PIB) did not differ with respect to sex (46% males in SOF/VEL group, and 51% in GLE/PIB group, $p = 0.62$) and age (10.0 ± 2.5 vs. 9.3 ± 3.2 years, $p = 0.18$). Most children were infected vertically (94% and 93%, $p = 0.8$), mainly with genotype 1 HCV (74% and 61%, $p = 0.31$) followed by genotype 3 and 4. Most children were treatment-naïve (94% vs. 98%, $p = 0.41$). At baseline, median alanine aminotransferase (ALT) levels did not differ: 48 IU/L (IQR 34–65) vs. 47 IU/L (35–68), $p = 0.84$, similarly to the HCV viral load (mean \log_{10} 5.8 ± 0.79 IU/ml vs. 5.9 ± 0.97 IU/ml, $p = 0.36$). One child in SOF/VEL group and 2 in GLE/PIB group presented with significant fibrosis (F2–3 in METAVIR scale). SVR12 was 100% in both groups. At 4-week of treatment, 2/50 (4%) patients in SOF/VEL group and 7/41 (17%) in GLE/PIB group presented with detectable HCV RNA ($p = 0.03$), but all were negative at the end of treatment. The most intense decrease in ALT level occurred during the first 4 weeks of treatment and it was similar in both groups [29 IU/L (14–43) vs. 28 (14–43) IU/L, $p = 0.94$]. Adverse events (AEs) were reported in 40% of patients in SOF/VEL group compared to 41.5% in GLE/PIB group ($p = 0.96$). The most common AEs included headache, abdominal pain, fatigue, asthenia, and somnolence. Asthenia occurred only in the SOF/VEL group (12%, $p = 0.02$), whereas skin itching only in GLE/PIB group (7%, $p = 0.05$).

Conclusion: Both pangenotypic regimens were 100% effective. The prevalence of AEs was similar in both groups. Thus, no superiority of any of the studied regimens for treatment of CHC in children was revealed.

THU-389

Sustained virological response after early discontinuation of HCV treatment

Robert Flisiak¹, Dorota Zarębska-Michaluk², Ewa Janczewska³, Anna Parfieniuk-Kowderda¹, Włodzimierz Mazur⁴, Marek Sitko⁵, Justyna Janocha-Litwin⁶, Rafał Krygier⁷, Beata Lorenc⁸, Anna Piekarska⁹, Barbara Sobala-Szczygieł¹⁰, Krystyna Dobrowolska², Łukasz Socha¹¹, Jerzy Jaroszewicz¹⁰. ¹Medical University of Białystok, Białystok, Poland; ²Jan Kochanowski University, Kielce, Poland; ³ID Clinic, Mysłówice, Poland; ⁴Medical University of Silesia, Chorzów, Poland; ⁵Jagiellonian University, Kraków, Poland; ⁶Wrocław Medical University, Wrocław, Poland; ⁷NZOZ Gemini, Żychlin, Poland; ⁸Medical University of Gdańsk, Gdańsk, Poland; ⁹Medical University of Łódź, Łódź, Poland; ¹⁰Medical University of Silesia, Bytom, Poland; ¹¹Pomeranian Medical University, Szczecin, Poland
Email: robert.flisiak1@gmail.com

Background and aims: So far, the effectiveness of therapy with direct-acting antivirals (DAA) discontinued before 4 weeks has not been analyzed in clinical practice. The aim of this study is to determine to what extent such a short therapy will enable achieving a sustained virological response (SVR) under real-world experience.

Method: Of the 16, 815 patients registered in the EpiTer-2 national database, 195 patients (1.2%) discontinued therapy, of which 97 had both the assessment of SVR and the time of discontinuation of therapy available.

Results: The majority (63.9%) patients discontinued treatment after 4 weeks, but 37 discontinued before the end of 4th week, including 12 within 2 weeks. The most common reason for therapy discontinuation was hepatic decompensation (20.6%) or the patient's personal decision (18.6%), and less frequently increased transaminase activity, cardiovascular or gastrointestinal symptoms, and anemia. Patients who discontinued therapy compared to those who completed treatment as planned were significantly older, more likely to have experienced prior therapy failure, more frequently have cirrhosis, a history of decompensation, and a Child-Pugh classification of B or C. SVR was achieved by 93.5% of patients who discontinued treatment after 4 weeks, 60.9% if discontinued at week 3 or 4 and 33.3% at week 1 or 2. The SVR rate after pangenotypic treatment in patients who discontinued after week 4 (100%) did not differ significantly from that observed in patients who completed the therapy planned (97.4%).

However, SVR after discontinuation before week 4 compared to discontinuation after that time was significantly lower in both pangenotypic (42.9% vs 100%) and genotype-specific (57.1% vs 92.5%) treated patients. The characteristics of four patients who responded to treatment lasting no longer than 2 weeks suggested that the main positive prognostic factor was a low baseline viral load (<400, 000 IU/ml).

Conclusion: Despite discontinuation of therapy after the 4th week of treatment, the chances of achieving SVR are high and even very early discontinuation of therapy does not exclude therapeutic success, especially in patients with low baseline viral load.

THU-390

Achieving HCV elimination in underserved populations-an austrian initiative for HCV care for homeless people without medical insurance

Caroline Schwarz^{1,2}, Bernadette Becsi³, Stephan Leick³, Stephan Gremmel³, Lena Wien⁴, Enisa Gusic¹, Thomas Reiberger², Hans Haltmayer⁵, Michael Gschwantler^{1,4}. ¹Klinik Ottakring, Vienna, Austria; ²Medical University of Vienna, Vienna, Austria; ³neunerhaus Gesundheitszentrum, Vienna, Austria; ⁴Sigmund Freud University, Vienna, Austria; ⁵Suchthilfe Wien gGmbH, Vienna, Austria
Email: schwarz.caroline1990@gmail.com

Background and aims: Direct-acting antiviral agents (DAA) facilitate excellent sustained virologic response (SVR) rates, yet reaching HCV elimination in Austria remains challenging. People experiencing homelessness (PEH) and/or lack of medical insurance (PELI) are at risk for HCV infection, however, specific elimination projects have not been designed for this population. We present the first Austrian HCV elimination project for PEH and PELI.

Method: The project was based at a low-threshold institution (LTI) providing medical care, social support, and housing for >5.000 PEH and PELI in Vienna per year. AntiHCV screening was offered at the LTI or one of its associated 27 housing institutions since 03/2020. AntiHCV (+) blood samples were further tested for HCV-RNA by PCR ("reflex testing"). HCV-viremic persons received DAA via a hepatitis outpatient clinic integrated in the LTI. PEH were provided with housing via the LTI for the duration of therapy, and in PELI treatment was kindly provided by Abbvie® or Gilead®. Adherence to DAA therapy, was supported by social workers of the LTI and in the respective housing facilities.

Results: Between 03/2020 and 07/2023, 601 individuals underwent serologic testing for HCV, and 116 (19.3%) showed antiHCV (+). While in 24/116 (20.7%) persons HCV-RNA PCR remained negative indicating resolved HCV infection, 92 (79.3%) were HCV-viremic. Among these, DAA therapy was initiated in 36/92 (39.1%) so far. At database closure (07/2023), 21/36 (58.3%) persons had completed DAA treatment and SVR was documented in 17 (81.0%), while 4 (19.0%) individuals remained on post-treatment follow-up. No DAA treatment interruptions were observed.

Conclusion: While the COVID19 pandemic limited the number of PEH and PELI reached by our screening effort, a substantial proportion of this underserved population underwent HCV testing through this project. HCV seroprevalence was 19.3%, HCV viremia exceeded expectations with 79.3% (tested) and 15.3% (overall)-underlining the relevance of targeted HCV care for PEH and PELI. Our data show that streamlined treatment with DAA is highly effective in the population of PEH and PELI, however, given that additional supporting measures are taken including social worker assistance and provision of safe housing for the duration of therapy. Future HCV elimination efforts should include the underserved population of PEH and PELI in whom HCV prevalence seems alarmingly high despite the availability of DAA. This study was supported by Abbvie® and Gilead®.

Impact of hepatitis C cure on outcomes for patients undergoing curative therapy for hepatocellular carcinoma

Alex Wynne¹, Edward J. Gane², Akhilesh Swaminathan³. ¹Auckland City Hospital, Auckland, New Zealand; ²Faculty of Medicine, University of Auckland, Auckland, New Zealand; ³Auckland City Hospital, Liver Unit, Auckland, New Zealand
Email: alexwynne25@gmail.com

Background and aims: Direct-acting antivirals (DAA) with high cure rates have had a dramatic impact on hepatitis C virus (HCV) and its complications, including reduction in incidence of index hepatocellular carcinoma (HCC). However, the impact on outcomes of hepatitis C cure for patients receiving curative intent treatment for their initial HCC is currently not known. Our aim is to assess the impact of hepatitis C cure on incidence of further (recurrent or metachronous) HCC, and on survival, in individuals who have undergone curative intent treatments.

Method: We conducted retrospective analysis of all patients that have received curative intent treatment (surgical resection or ablation) for HCC secondary to HCV in New Zealand between 2003 and 2023. We compared outcomes of those who achieved sustained viral response (SVR) prior to HCC treatment with those who had not achieved SVR prior. We used Kaplan Meier comparison of recurrence free survival and overall survival using Log-Rank and univariable and multivariable analysis using Cox Regression.

Results: Of the 203 patients included in the analysis, 56% had achieved SVR prior to or at the time of their HCC diagnosis. Our analysis showed that achieving SVR prior to initial HCC therapy reduces risk of HCC recurrence compared to never achieving SVR (Hazard Ratio (HR)=0.44, 95% Confidence Interval (CI) 0.26–0.64). Our analysis also showed that patients achieving SVR prior to the initial HCC therapy reduces the risk of death compared to those not having achieved SVR (HR = 0.36, 95% CI 0.21–0.64).

Conclusion: These results demonstrate that eradication of HCV infection in patients who present with their index HCC reduces the risk of recurrent HCC following resection or ablation by almost 60%. In the era of highly effective DAA therapy and limited supply of deceased donors, patients with HCV infection who have been diagnosed with their index HCC should be treated with DAAs and offered resection or ablation rather than transplantation.

THU-394

Improvement of hepatitis C virus care cascade by In-hospital Reflex tEsting ALarm-C (REAL-C) model

Jonggi Choi¹, Kanghee Park¹, Jina Park¹, Ji won Yang¹, Hyeeyeon Hong¹, Sung Won Chung¹. ¹Asan Medical Center, Seoul, Korea, Rep. of South
Email: jkchoi0803@gmail.com

Background and aims: World Health Organization (WHO) has set targets to eliminate viral hepatitis, including hepatitis C virus (HCV) infection, by 2030. Achieving these goals necessitates improved rates of diagnosis and treatment. We present the results of the in-hospital Reflex tEsting ALarm-C (REAL-C) model, which incorporates reflex HCV RNA testing and sending alarming messages for physicians.

Method: We conducted a retrospective study at Asan Medical Center in Seoul, Republic of Korea, focusing on 1,730 patients newly testing positive for anti-HCV between March 2020 and June 2023. Three distinct periods were defined: pre-REAL-C (n = 696), incomplete REAL-C (n = 515), and complete REAL-C model periods (n = 519). The primary outcome measured was the rate of HCV RNA testing throughout the study period. Additionally, the referral rate to gastrointestinal (GI) department, linkage time for diagnosis and treatment, and the treatment uptake rate.

Results: The rate of HCV RNA testing increased significantly from 51.0% (pre-REAL-C) to 95.6% (complete REAL-C). This improvement was consistent across clinical departments, regardless of patients' comorbidities. Among patients confirmed with HCV infection, the GI referral rate increased from 57.1% to 81.1% after the implementation of

the REAL-C model. Treatment uptake rates among treatment-eligible patients was 92.4% during the study period. The mean days from anti-HCV positivity to HCV RNA testing decreased from 45.1 to 1.9. The mean days from the anti-HCV positivity to direct-acting antiviral treatment also decreased from 89.5 to 49.5 with the REAL-C model. **Conclusion:** The REAL-C model, featuring reflex testing and alarming messages, effectively increased HCV RNA testing rates and streamlined care cascades. Our model facilitated progress toward achieving the WHO's elimination goals for HCV infection.

THU-395

Is hepatitis C screening based on risk factors enough in primary care setting?

Elena Vargas-Accarino¹, Ariadna Rando-Segura², Ingrid Arcusa³, Eva de Diego⁴, Núria García⁵, Elena Monserrat⁶, Marta Selvi⁷, Maria Asuncion Ubieda Pastor⁴, Imma Valls⁸, Carla Ventosa⁹, Adriana Palom¹, Judit Romero-Vico¹, Juan Carlos Ruiz-Cobo^{1,10,11}, Mar Riveiro Barciela^{1,10,11,12}, Rafael Esteban^{1,10,11,12}, Maria Buti^{1,10,11,12}. ¹Liver Diseases Research Group, Vall d'Hebron Research Institute, Barcelona, Spain; ²Microbiology and Biochemistry Department, Vall d'Hebron University Hospital, Barcelona, Spain; ³CAP Trinitat Vella, Barcelona, Spain; ⁴CAP Horta, Barcelona, Spain; ⁵CAP Río de Janeiro, Barcelona, Spain; ⁶CAP Chafarinas, Barcelona, Spain; ⁷CAP Sant Andreu, Barcelona, Spain; ⁸CAP San Rafael, Barcelona, Spain; ⁹CAP Guineueta, Barcelona, Spain; ¹⁰Liver Unit, Vall d'Hebron University Hospital, Barcelona, Spain; ¹¹Medicine Department, Universitat Autònoma de Barcelona, Barcelona, Spain; ¹²CIBERehd, enfermedades hepáticas y digestivas, Madrid, Spain
Email: mariabutiferret@gmail.com

Background and aims: Most international guidelines recommend HCV screening only for individuals with risk factors or elevated ALT. These recommendations are based on descriptive studies in which it was identified that more than 80% of patients with positive anti-HCV had risk factors. However, screening strategies based on risk factors may be insufficient for eradicating the infection in high-income countries, since the undiagnosed population remains stable. The objective of our study was to evaluate the application of hepatitis C screening guidelines in primary care centers (PCC) in Spain.

Method: Retrospective search in the microbiology database of the anti-HCV+ and HCV-RNA+ patients from 7 primary care centers. Medical records of those patients were reviewed to assess the screening recommendation application and treatment indication.

Results: Of a total of 90,170 different individuals who attended these 7 primary care centers, 9,052 (10%) were screened for hepatitis C between January 2021 and March 2023. Anti-HCV antibodies were detected in 277 (3%) individuals and 48 (7%) were HCV-RNA+, accounting for 0.5% of the screened patients. Medical records of those 277 anti-HCV+ patients were reviewed to analyze their screening criteria. We found that only 38% of anti-HCV+ patients reported risk factors. Of them, 19% were people who inject drugs, 9% had a previous blood transfusion, 4% had tattoos, 4% had sexual risk behavior and 2% were infected by vertical transmission. Analyzed by transaminases levels, 76% had normal transaminases and 24% presented elevated AST or ALT. When analyzed together, we found that 150 (54%) anti-HCV+ patients neither reported risk factor nor presented elevated transaminases. From the 48 HCV-RNA+ patients, only 42% reported risk factors and 31% elevated transaminases; while analyzing it together we found that 22 (46%) of them neither reported risk factors nor elevated transaminases. Anti-HCV+ participants were 55% male, median age 59 years and 70% were born in Spain. Basal median AST and ALT were 29 and 35 IU/L respectively and had FIB-4 and APRI of 2.2 and 0.4 respectively. However, HCV-RNA+ cases were mainly male (60%), older (median age of 69 years) and had higher AST and ALT levels (41 and 47 IU/L respectively) and FIB-4 and APRI of 0.85 and 0.45, respectively. Age and transaminases were significantly higher in individuals with HCV-RNA (p < 0.05).

Conclusion: Only 10% of patients attending primary care centers are screened for hepatitis C, with 0.5% of these patients being viremic. More than a half of anti-HCV+ patients neither reported risk factors nor had elevated transaminases and they would not have been screened for hepatitis C if following current guidelines. Moreover, almost a half of HCV-RNA+ patients would not have been treated. HCV universal screening in PCC could be a good strategy to eliminate hepatitis C.

THU-396

HCV patients achieving sustained virologic response after direct-acting antiviral therapy may still face adverse clinical outcomes: analysis of gene enrichment, marker expression, and clinical outcomes

Daniel Millian¹, Omar Saldarriaga², Esteban Arroyave², Heather Stevenson³, Arvind Rao⁴, Santhoshi Krishnan⁴. ¹University of Texas Medical Branch, Galveston, Texas, United States; ²University of Texas Medical Branch, Galveston, Texas, United States; ³University of Texas Medical Branch, Galveston, Tx, United States; ⁴University of Michigan, Michigan, United States
Email: damillia@utmb.edu

Background and aim: The incidence of HCV in the United States is on the rise, driven by the opioid epidemic, and even though over 95% of HCV patients respond positively to direct-acting antiviral (DAA) therapy they continue to be at risk of re-infection, and chronic liver disease. In this study, we explore the complex aftermath of DAA treatment for Hepatitis C, focusing on the observation where patients achieving sustained virologic response (SVR) may still face adverse clinical outcomes, including portal hypertension and hepatocellular carcinoma. We aim to determine the gene and protein expression of the hepatic microenvironment before and after DAA treatment to identify key biological markers associated with poor outcomes.

Method: Utilizing cutting-edge multispectral imaging, we scrutinize the nuances of intrahepatic macrophage (CD68, CD14, CD16, MAC387, and CD163) and T cells (CD3, CD4, CD8, CD45, and FoxP3) phenotypes. This involves the comparison of liver biopsies collected before (n = 10) and after (n = 10) SVR attainment (5 were paired biopsies from the same patients; total of 15 patients). Employing advanced imaging analysis and machine learning algorithms, we decoded the changes in these pivotal immune cells. Furthermore, our exploration extends to over 700 genes through RNA isolated from liver biopsies using NanoString nCounter and RNA sequencing (SMART-seq). Both platforms were correlated with clinical outcomes.

Results: The pre and post-treatment (Pre-Tx, Post-Tx) fresh liver tissue data from 15 patients were analyzed and correlated with clinical outcomes. We observed that in the post-Tx liver biopsies of patients without inflammation, the liver enzymes aspartate aminotransferase (AST) (Pre-Tx 122 U/L, SD ± 105 and post-Tx 29 U/L, SD ± 10.3, respectively), and alanine aminotransferase (ALT) (Pre-Tx 96 U/L, SD ± 104 and Post-Tx 20 U/L, SD ± 27) returned to baseline compared to Pre-Tx values. This coincides with the multispectral imaging showing a switch from proinflammatory/M1-like to anti-inflammatory/M2-like macrophage phenotypes pre- and post-treatment, respectively. Nanostring gene expression analysis showed an enrichment of inflammatory and interferon-induced antiviral genes in the pre-treatment group when compared to the Post-Tx. However, after treatment, the fibrosis stage of 5 out of 15 patients did not improve or regress to baseline, and 2 out of these 5 patients died from decompensated cirrhosis and one succumbed to cholangiocarcinoma. These results were subsequently confirmed using RNA sequencing.

Conclusion: In summary, this work reveals distinctive gene and marker expression profiles before the administration of DAAs, which undergo notable changes post-treatment. However, patients with advanced fibrosis or with cirrhosis at the initiation of the antiviral therapy may develop poor clinical outcomes even after achieving sustained virologic response.

THU-397-YI

Long-term histological fibrosis evolution following sustained virological response after hepatitis C-recurrence in liver-transplanted patients

Tibo Lemmens¹, Cindy Serdjebi², Guillaume Henin¹, Selda Aydin¹, Pamela Baldin¹, Florine Chandès², Géraldine Dahlqvist¹. ¹Cliniques universitaires Saint Luc, Brussels, Belgium; ²Biocellvia, Marseille, France
Email: tibolemmens123@gmail.com

Background and aims: Hepatitis C (HCV) recurrence after liver transplantation (LT) is universal if HCV-RNA persists at time of LT and progression to fibrosis can occur rapidly. Nowadays, sustained virological response (SVR) is obtained in 97% of HCV-infected patients treated with direct acting antivirals (DAA) after LT. Fibrosis diminishes in HCV patients after SVR but there is paucity of data on fibrosis regression occurring after SVR following LT. In addition, most studies evaluate fibrosis with non-invasive techniques while these are not validated after LT because of LT-specific complications. There are no data evaluating long-term evolution of fibrosis after SVR since the introduction of DAA treatments (>5–10 years). The aim of this study is to histologically evaluate liver fibrosis evolution in short and long term follow-up biopsies after HCV-elimination in LT-patients.

Method: In this retrospective monocentric cohort study, we evaluated 32 patients with SVR after recurrent HCV following LT and treated with IFN (n = 4) or DAA (n = 28). Protocolar liver biopsies were collected between 2011 and 2020. We compared liver biopsies before HCV treatment, with those taken during short-term follow-up (<2 years) and long-term follow-up (≥3 years). Massons' trichrome (MTC) slides were used for METAVIR- and LAF scoring. Picro-Sirius-red (PSR) slides were used for both a semi-quantitative assessment of fibrosis expressed as total fibrosis area (%) and an automated morphometric assessment of fibrosis with artificial intelligence (AI) based technology MorphoQuant.

Results: All 32 patients reached SVR after LT, including 24 with follow-up biopsies. Scoring and AI-based analyses were performed on 19 and 24 patients, respectively. PSR analysis showed a significant reduction in total fibrosis area on the short-term biopsies (−4.9%, p < 0.002) in 73% of patients, which remained stable even after long-term assessment (−4.9%, p < 0.001). MTC based scoring confirmed fibrosis regression in the long-term biopsies, according to either METAVIR (−0.8, p < 0.01) or LAF-Score (−1.5, p < 0.02) but not in the short-term biopsies. AI-based analysis showed a significant reduction of collagen proportionate area in the short-term biopsies after HCV treatment, and a stabilization over time (−3.2%, p < 0.001). This reduction was notably significant in the perivascular area (−2.5%, p < 0.002), but not in the peri-sinusoidal or septal area. Finally, collagen fibres were smaller after short-term evaluation (−0.18%, p < 0.02), which was confirmed in long-term follow-up biopsies.

Conclusion: Achieving SVR after post-LT HCV-recurrence results in swift reduction of fibrosis with stabilization on the long term. AI-based analyses show earlier changes than the classical histological scoring systems.

THU-398

Metabolic factors predict significant liver fibrosis in people who use drugs (PWUD) and general population with HCV infection. Time to re-consider the follow-up strategy in chronic hepatitis C patients

Hariklia Kranidioti¹, Olga Anagnostou², Georgios Kontos¹, Sofia Vasileiadi¹, Anestis Goulas¹, Nikolaos Papadopoulos^{3,4}, Melanie Deutsch¹, Spilios Manolakopoulos¹. ¹2nd Department of Internal Medicine, National and Kapodistrian University of Athens, General Hospital of Athens Hippocratio, Athens, Greece; ²Greek Organization against of Drugs (OKANA), Athens, Greece; ³401 General Army Hospital of Athens, Athens, Greece; ⁴401 General Army Hospital of Athens, 2nd Department of Internal Medicine, Athens, Greece
Email: harakranidioti@yahoo.gr

POSTER PRESENTATIONS

Background and aims: Comorbidities related to metabolic syndrome are associated with liver fibrosis and affect the management and surveillance of patients with HCV infection. The aim of the study was to address the prevalence of metabolic risk factors in HCV patients and their impact on liver stiffness according to the source of infection.

Method: We included patients with detectable HCV RNA who received treatment with DAAs in our outpatient liver clinic from June 2014 to July 2021. Metabolic profile was based on BMI measurement, medical records and prescribed medication for diabetes mellitus (DM), arterial hypertension (AH) and dyslipidemia (DLD) on baseline evaluation. Liver stiffness was evaluated with transient elastography (TE).

Results: 680 patients were analyzed (71% males, 51 ± 12 years old, 57% >50 years old). 422 (62%) patients reported previous history of drug use (PWUD) and 71% was under substitution with buprenorphine or methadone. Regarding metabolic risk factors, 41 (6%) patients presented DM, 215 (32%) AH, 80 (12%) DLD and 275 (40%) had BMI >25 (mean BMI 24.9 kg/m²). Compared with PWUD, patients who had HCV infection from other sources (general population) were older (56 vs 47 years, $p < 10^{-3}$), had higher BMI (26 vs 24 kg/m², $p < 10^{-3}$), and presented more frequently DM (12.7% vs 1.7%, $p < 10^{-3}$), AH (24% vs 12%, $p < 10^{-3}$) and DLD (12.7% vs 1.9%, $p < 10^{-3}$). In total, 327 (51%) patients (43% PWUD vs 61% general population, $p < 10^{-3}$) had significant fibrosis or cirrhosis (liver stiffness >9 kPa). Logistic regression analysis revealed that predictive factors for significant fibrosis were source of infection (general population) ($p < 10^{-3}$), older age ($p < 10^{-3}$), BMI ($p < 10^{-3}$), BMI >25 kg/m² ($p < 10^{-3}$), AH ($p = 0.01$), and the presence of DM ($p < 10^{-3}$). In multivariate analysis, age and BMI were the only independent predictive factors. Sub-cohort analysis for PWUD and general population separately for individuals >or <50 years old, showed that BMI was the only independent predictive factor for significant fibrosis ($p < 10^{-3}$). Liver stiffness addressed an independent positive predictive value ($p = 0.04$) for poor outcome (liver related death or hepatocellular carcinoma).

Conclusion: Our data postulated that metabolic factors could predict significant fibrosis in patients with HCV infection. BMI represents an independent risk factor for significant fibrosis regardless the source of infection and the older age. The presence of metabolic factors should be taken under consideration for the management and follow-up of the chronic HCV patients.

THU-399-YI

Burden of extrahepatic manifestations after HCV cure: assessing the effect of IFN versus DAA-induced SVR in a large population-based cohort in British Columbia, Canada

Dahn Jeong¹, Stanley Wong², Jean Damascene Makuza¹, Héctor Alexander Velásquez García^{1,2}, Mel Kraijden³, Richard Morrow¹, Prince Adu², Sofia Bartlett^{1,2}, Georgine Cua⁴, Amanda Yu², Maria Alvarez², Naveed Janjua^{1,2}. ¹School of Population and Public Health, University of British Columbia, Vancouver, Canada; ²BC Centre for Disease Control, Vancouver, Canada; ³Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, Canada; ⁴Faculty of Medicine, University of British Columbia, Vancouver, Canada
Email: dahn.jeong@bccdc.ca

Background and aims: Prior research indicates that hepatic and extrahepatic damage from chronic HCV infection may persist post-virologic cure. While evidence supports HCV treatment benefits in reducing the risk of extrahepatic manifestations (EHMs) among individuals achieving sustained virologic response (SVR) compared to those living with untreated HCV, the burden of EHM after SVR remains unclear. Moreover, differences in health outcomes after interferon (IFN) vs direct-acting antiviral (DAA)-based SVR have been suggested. This analysis assessed the EHM burden among individuals achieving SVR through IFN or DAA treatment in a large, population-based cohort.

Method: We used the British Columbia Hepatitis Testers Cohort (BC-HTC), which includes all individuals diagnosed with HCV from 1990 to 2015, linked with administrative health datasets. Our study sample included individuals receiving IFN or DAA treatment with confirmed SVR. EHM diagnoses were obtained through ICD-9/10 diagnostic and procedure codes in hospitalization and physician billing data, including chronic kidney disease (CKD), type 2 diabetes (DM), major adverse cardiac events (MACE), neurocognitive disorders (NCD) and mood and anxiety disorders (MAAD). We computed incidence rates (IR) of EHMs by treatment type from the date of SVR assessment. To address the differences in baseline sociodemographic and clinical characteristics between people treated with IFN or DAA, we adopted inverse probability of treatment weighting (IPTW) to induce balance across characteristics. Multivariable subdistribution hazard models, weighted with IPTW and accounting for competing mortality risks, were used to estimate risk of incident EHMs.

Results: Study sample included 4,551 persons treated with IFN and 10,819 persons treated with DAA, with confirmed SVR. Those treated with DAA were younger, more likely to have a history of drug and alcohol use disorder, with a greater prevalence of EHMs prior to SVR compared to individuals treated with IFN. Persons treated with DAA had a higher IR of CKD, MACE and NCD compared to those treated with IFN. The IR of DM and MAAD didn't differ between people treated with IFN or DAA. When adjusting for differences in baseline characteristics with IPTW and competing mortality risks, people treated with IFN had reduced risks of CKD, MACE and NCD, but higher risk of DM and MAAD compared to those treated with DAA; adjusted subdistribution hazard ratios: CKD 0.68 (95% CI 0.57–0.80), DM 1.37 (95% CI 1.10–1.69), MACE 0.60 (95% CI 0.53–0.69), NCD 0.56 (95% CI 0.47–0.68) and MAAD 1.49 (95% CI 1.24–1.79).

Conclusion: Individuals who were treated with DAA had higher EHM burden before and after virologic cure compared to those treated with IFN. Given the shift to DAA treatments, further research is needed to understand pre-therapeutic EHM risk factors and the impact of curative therapy on EHMs and overall long-term health outcomes.

THU-402

Higher cardiovascular burden in people living with HIV (PLWH) with metabolic syndrome and history of HCV infection

Alessia Siribelli¹, Michele Bellomo², Camilla Muccini², Riccardo Lolatto², Giulia Morsica², Sara Diotallevi², Nicola Gianotti², Simona Bossolasco¹, Costanza Bertoni¹, Vincenzo Spagnuolo¹, Antonella Castagna³, Hamid Hasson¹. ¹San Raffaele Scientific Institute, Milan, Italy; ²San Raffaele Scientific Institute, Milan, Italy; ³Vita-Salute San Raffaele University, San Raffaele Scientific Institute, Milan, Italy
Email: siribelli.alessia@hsr.it

Background and aims: People living with HIV (PLWH) have higher occurrence of major adverse cardiovascular events (MACE). This study aimed to identify factors associated with MACE in PLWH during a 10-years (yrs) follow-up (FU).

Method: Retrospective study including PLWH followed at San Raffaele Scientific Institute, Italy, between January 2013–December 2023, with at least 3 observations for laboratory data. Metabolic syndrome (MetS) defined according to ATP3 criteria (NCEP). MACE considered were myocardial infarction, unstable angina, stroke, transient ischemic attack, peripheral arterial ischemia, revascularization. Trained binary classification algorithm (simple logistic regression), calculating at each examination the probability of developing at least one MACE within the following year was used. To adjust for residual variability of developing MACE, generalized additive mixed model (GAMM), with random intercept and non-parametric model of variables was used. Continuous variables as age, yrs of MetS, Log HIV viremia and CD4 were modelled with smooth effects, the remaining with standard regression coefficients.

Results: Overall, 5416 PLWH were included: 4363 (81%) were males, 3088 (58%) smokers or ex, 2437 (45%) had MetS, HBV and HCV

coinfection were diagnosed in 377 (7%, of which 1.9% not virologically suppressed) and 1076 (20% of which 1.8% untreated), respectively. During a median FU of 9.7 yrs, 216 (4%) developed at least one MACE. In simple logistic regression, higher occurrence of MACE was significantly associated with age (OR = 1.06;95%CI = 1.04, 1.07; p < 0.0001), male sex (OR = 2.29;95%CI = 1.64, 3.28; p < 0.0001), presence of MetS (OR = 1.72;95%CI = 1.27, 2.29; p < 0.0003), smoking (OR = 2.01;95%CI = 1.58, 2.56; p < 0.0001), co-presence of HCV with MetS (OR = 1.72;95%CI = 1.09, 2.72; p = 0.021), use of protease inhibitors (PI) (OR = 2.1;95%CI = 1.45, 3.03; p < 0.0001) and integrase inhibitors (INSTI) (OR = 1.34;95%CI = 1.03, 1.73; p = 0.0274). In GAMM, age (p = 0.0001), male sex (OR = 2.23;95%CI = 1.46, 3.41; p = 0.0002), smoking (OR = 1.91;95%CI = 1.39, 2.62; p < 0.0001), use of PI (OR = 1.65;95%CI = 1.06, 2.58; p = 0.0278) confirmed to increase occurrence of MACE.

Conclusion: In a large cohort of PLWH, during 10-yr of FU, MACE are more likely to occur in people with MetS and history of HCV infection, additionally to traditional factors and specific HIV therapy. Surveillance and appropriate management of MetS, particularly in people coinfecting with HCV-HIV, could help reduce cardiovascular burden.

THU-403

Liver fibrosis and steatosis in children after effective treatment of chronic hepatitis C using direct acting antivirals

Maria Pokorska-Śpiwak¹, Ewa Talarek², Anna Dobrzyńska³, Małgorzata Aniszewska⁴, Magdalena Pluta¹, Magdalena Marczyńska¹.
¹Medical University of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland; ²Medical University of Warsaw, Warsaw, Poland; ³Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland; ⁴Medical University of Warsaw, Regional Hospital of Infectious Diseases in Warsaw, Warsaw, Poland
 Email: maria.pokorska-spiwak@wum.edu.pl

Background and aims: In this study we aimed to examine the long-term influence of successful treatment with direct acting antivirals (DAAs) on liver fibrosis and steatosis in children with chronic hepatitis C (CHC).

Method: Of 135 children aged 5 to 18 years who had been treated with DAAs due to CHC in our Department between July 2019 and December 2023 as a part of two projects: PANDAA-PED (12-week treatment with sofosbuvir/velpatasvir, SOF/VEL) and POLAC Project (12/24-week treatment with sofosbuvir/ledipasvir, SOF/LDV, and 8-week with glecaprevir/pibrentasvir, GLE/PIB), we selected successfully treated participants, who completed control evaluation at one-year posttreatment. Liver fibrosis and steatosis were assessed using transient elastography at baseline, 12-week posttreatment, and one-year posttreatment. Significant fibrosis was diagnosed when liver stiffness measurement (LSM) was >7 kPa, cirrhosis when LSM was ≥12.5 kPa, and steatosis when controlled attenuation parameter (CAP) was >238 dB/m.

Results: We identified 67 patients (32 boys, 48%) eligible for the study: 49 after SOF/VEL treatment, 9 after GLE/PIB, and 9 after SOF/LDV. At baseline, the mean age was 10.4 ± 2.9 years. There were 62 (93%) patients infected vertically, 58 (87%) were treatment-naïve, 41 (61%) were infected with genotype 1. All children had undetectable HCV RNA at one-year posttreatment. At baseline, 5/67 (7%) participants presented with significant fibrosis, including 2 with cirrhosis. At 12-week posttreatment, only 2 of these patients had LSM >7 kPa, and one-year posttreatment only one cirrhotic patient had abnormal LSM. Mean values of LSM for the study group were 4.9 kPa (95%CI 4.4–5.4) at baseline, 4.8 kPa (3.9–5.8) at 12-week posttreatment, and 4.5 kPa (3.8–5.3) at one-year posttreatment (all p > 0.05), whereas corresponding CAP values were 180 dB/m (170–191), 195 dB/m (185–206), and 191 dB/m (180–201), respectively (for the first two values p = 0.009). Number of patients with steatosis increased from 4 (6%) at baseline to 7 (10%) at 12-week posttreatment, and to 8 (12%) at one-year posttreatment.

Conclusion: Successful treatment with DAAs leads to regression of significant liver fibrosis in most cases. Increased CAP values after therapy require further analysis on larger groups of patients.

THU-404

Impact of hepatitis C treatment on mortality among liver cancer patients in Georgia-2015–2022

Anna Khoperia¹, Maia Butsashvili², Shaun Shadaker³, Susan Gawel⁴, Sophia Surguladze⁵, Nazibrola Chitadze¹, Konstantine Kazanjan¹, Vladimer Getia¹, Lasha Gulbiani², Geoff Beckett⁶, Alan Landay⁷, Maia Tsereteli¹, Maia Alkhazashvili¹, Amiran Gamkrelidze⁸, Francisco Averbhoff⁴.
¹National Center for Disease Control and Public Health, Tbilisi, Georgia; ²Health Research Union, Tbilisi, Georgia; ³Centers for Disease Control and Prevention, Atlanta, United States; ⁴Abbott Diagnostics, Illinois, United States; ⁵The Task Force for Global Health, Tbilisi, Georgia; ⁶Centers for Disease Control and Prevention, Retired, Atlanta, United States; ⁷Rush University, Chicago, United States; ⁸University of Georgia, School of Health Sciences, Tbilisi, Georgia
 Email: annakhoperia@gmail.com

Background and aims: Chronic hepatitis C virus (HCV) infection can result in hepatocellular carcinoma (HCC), the most common form of primary liver cancer (PLC). The country of Georgia has an HCV elimination program providing testing and treatment since 2015. This study uses data from national registries to assess the association of HCV infection and treatment with mortality in individuals with documented history of liver cancer in Georgia.

Method: We conducted a retrospective registry-based cross-sectional study of adult (≥18 years) liver cancer cases in the Georgian Cancer Registry (GCR) during January 2015–December 2022 linked to HCV screening and treatment data using unique national IDs. HCC, defined as ICD-10 of C22.0, was compared to other PLC cases (ICD-10 C22.1–C22.9). Mortality was defined as a recorded death date at the time of analysis. We conducted bivariable and multivariable analyses to compare mortality proportion between the HCC subtype versus other liver cancer subtypes, explore differences in mortality of cases with and without HCV history, and the correlation between HCV treatment and mortality in the HCV-infected subgroup. Logistic regression modeling assessed factors associated with mortality: age, sex (female vs. male), achievement of sustained viral response (SVR) after treatment (yes vs. no), and GCR-assigned liver cancer ICD-10 code (HCC vs. other types of liver cancer). Odds ratios (OR) and 95% confidence intervals (CI) were calculated. Cases with missing vital status were excluded.

Results: Of 1736 adults with PLC, 1388 (79.9%) were deceased at the time of analysis. Although age was associated with increased mortality (OR = 0.7, 95% CI [0.6–0.8]), a statistically significant association was not found between sexes. HCC was reported among 419 (24.1%) PLC cases. Compared to HCC cases, other combined subcategories of liver cancer (OR = 2.1, 95% CI [1.6–2.8]) were associated with increased mortality. Overall, 1393 (80.2%) PLC cases were screened for anti-HCV, and out of 717 (51.5%) tested for viremia, 655 (91.4%) were HCV RNA positive; of those, 495 (75.6%) initiated HCV treatment and 445 (89.9%) completed. No statistically significant differences were observed in mortality between anti-HCV reactive and non-reactive groups with documented PLC. Logistic regression analyses controlling for sex among PLC patients with viremic HCV infection, achievement of SVR (adjusted OR [aOR] = 2.04, 95% CI [1.04–4.17], p = 0.049) and having HCC compared to other liver cancers (aOR = 2.59, 95% CI [1.51–4.45], p < 0.001) were associated with reduced mortality.

Conclusion: While no statistically significant mortality associations were found between anti-HCV reactive and non-reactive cases with documented PLC, achieving sustained virologic response (SVR) is a potential factor associated with reduced mortality among liver cancer patients with a history of HCV infection.

THU-405

Analysis of a decentralized model interdisciplinary for the elimination of HCV in vulnerable population in the province of Huelva (Spain). To continue advancing in the elimination of hepatitis C, it is necessary to establish a clearly defined integrated care plan

Gema Romero¹, Ana Bejarano¹, Francisco Franco¹, Pilar Del Pino¹, María Dolores Santos¹. ¹Hospital Universitario Juan Ramón Jiménez, Huelva, Spain

Email: gemarherrerah@hotmail.com

Background and aims: the objective of this study is to evaluate the implementation of a comprehensive strategy of microelimination based on the decentralization of the diagnosis and treatment.

Method: prospective observational study in which screening of the HCV infection through rapid serological tests (saliva or whole blood samples), in settlements of immigrant workers in the agricultural campaign in the province of Huelva and people who go to centers that serve the vulnerable population in Huelva capital (Cáritas, center Red Cross of Torrejón meeting and reception and Virgen de la Cinta social lunchroom). In the detected positive, an "in situ" viremia study was performed (GeneXpert®). In patients viraemic, a comprehensive out-of-hospital assessment was carried out at the same time by the hepatologist with Fibroscan® and abdominal ultrasound with portable devices and dispensing of the antiviral treatment.

Results: 322 people were screened with close to 100% success in participating in each working day. The majority nationalities of the settlement population were Ghanaian (85), Morocco (70) and Romania (56). In the social centers the majority were Spanish population (64). 5 viremic patients were detected (prevalence of 1.5%), 4 being treated, not leading to treatment was carried out on one of the patients because a lesion was detected in the abdominal ultrasound suggestive of hepatocellular carcinoma. Among the viremic patients, the two detected in settlements were of Romanian origin, with an incidence of 3.5% in said population.

Conclusion: decentralization in virological diagnosis, medical care by experts in HCV and the provision of treatment is feasible and eliminates known barriers. It is necessary for them proactive multidisciplinary teams.

THU-406

Knowledge, perceptions and barriers to the diagnosis and treatment of hepatitis C among persons who inject drugs: findings from the Educate-Test-Treat (ETI) programme in Singapore

Alyssa Sim¹, Shann Long¹, Sanchalika Acharyya², Gerard Wong³, Ryan Jia Jie Liew⁴, Kuo Chao Yew¹. ¹Department of Gastroenterology and Hepatology, Tan Tock Seng Hospital, Singapore, Singapore; ²Clinical Research and Innovation Office (CRIO), Tan Tock Seng Hospital, Singapore, Singapore; ³HCSA Highpoint Halfway House, HCSA Community Services, Singapore, Singapore; ⁴Anglo Chinese School (Independent), Singapore, Singapore
Email: alyssasim@gmail.com

Background and aims: The World Health Organization (WHO) has implemented a global elimination strategy, setting a rate of ≥90% of chronic hepatitis C (HCV) being diagnosed to achieve eradication target goals by 2030. Its prevalence is high among people who inject drugs (PWID). Despite effective, simple oral Direct-Acting Antivirals (DAA), the uptake of diagnosis and treatment for HCV among PWID has been consistently low. We aimed to identify gaps in knowledge and attitudes in our local cohort and uncover local barriers towards achieving elimination of HCV.

Method: PWID from 4 halfway houses in Singapore were recruited from March 2022–April 2023. Using a structured questionnaire, information was gathered on baseline demographics and socio-economic status. We also assessed HCV awareness, knowledge, attitudes and perceptions regarding pursuit of treatment. Seven items were extracted from the questionnaire which pertained to

'knowledge' and 'attitude', each with a total score of 7 and classified into 'poor' (0–2), 'average' (3–5), or 'good' (6–7) for both domains. Statistical analysis was conducted on SPSS version 27 and statistical significance set at $p = 0.05$.

Results: Out of 198 participants, mean age was 54.0 years and 99% were male. Less than 20% of the participants had completed tertiary education. Participants with lower education levels were at greater risk of HCV infection, and although had poorer knowledge, demonstrated better attitude. 45.9% demonstrated average understanding of HCV. 35.9% were found to have poor understanding. The majority displayed good attitude (79.8%) and average attitude (20.2%). Notably, none displayed poor attitude. From univariate analysis, looking at knowledge and awareness of HCV, poor knowledge was associated with increasing age ($p = 0.018$) and lower education levels ($p = 0.034$). There were no significant differences in terms of these patient factors with regards to attitude. However, on multivariate analysis, increasing age (OR1.05, CI 1.01–1.09) $p = 0.02$ and increased knowledge scores (OR1.21, CI 0.98–1.49) $p = 0.073$ were associated with better attitude. When looking at potential barriers to the diagnosis and treatment of HCV, cost was the most important factor (56.6%), followed by side effects (39.5%) and perceived stigma (4.1%). We also identified venepuncture and saliva to be the preferred testing methods for HCV.

Conclusion: In conclusion, there are evident gaps in knowledge of HCV among PWID. It is essential to develop targeted education strategies in addressing misconceptions about HCV. Efforts to improve linkage to care should address barriers at different levels, and system-level changes are important. Targeting this may help us effectively achieve the HCV elimination goals in Singapore.

A new pattern for hepatitis C management in hospital: establishment and effectiveness verification

Dong Yan¹, Siheng Zhu¹, Xiaoting Ye², Heqing Huang³. ¹The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China; ²Ruian people's Hospital, Ruian, China; ³Zhuji people's Hospital of Zhejiang Province, Zhuji, China
Email: yandonh@zju.edu.cn

Background and aims: Viral hepatitis C is a kind of infectious disease caused by hepatitis C virus (HCV) infection. Statistics have shown that the rates of diagnosis and treatment coverage were not high. This study aims to establish a new management pattern of hepatitis C in hospital and verify whether it can improve the rates of diagnosis and treatment.

Method: A new management pattern of hepatitis C in hospital was established and promoted: First, newly-found HCV antibody positive patients were collected through our infection monitoring system every two weeks and followed regularly, then sorting out and analyzing the data; Second, real-time reminders were set up in the electronic case record system and on the results sheets, urging for specialized diagnosis and treatment; Third, all medical staff needed to receive training to improve their understanding of hepatitis C infection; Fourth, infectious disease report card of hepatitis C was specially added. The RNA testing rates and the treatment rates of hepatitis C in different periods were then compared.

Results: Before the new pattern, the total HCV-RNA testing rate was 68.79% (3002/4364), with the RNA positive rate of 51.53% (1547/3002), and the treatment rate was 32.35% (764/2362). The RNA testing rate of non-infectious disease departments was 52.89% (1363/2577). Among males, 1715/2441 (70.26%) tested RNA, while among females the rate was 1287/1923 (66.93%). The RNA testing rates in different age groups were as follows: aged 0 to 29–76.40% (437/572), aged 30 to 59–70.97% (1907/2687), aged 60 to 89–59.84% (657/1098), and aged 90 and above–14.29% (1/7). Under the new pattern, the total RNA testing rate increased to 86.84% (409/471), with the RNA positive rate of 78.48% (321/409), and the treatment rate achieved 65.00% (195/300). The RNA testing rate in non-infectious disease

departments reached 201/253 (79.45%). The RNA testing rates for males and females increased to 84.47% (261/309) and 91.36% (148/162) respectively. In the first three age groups, the RNA testing rates all increased, specifically: aged 0 to 29–92.11% (35/38), aged 30 to 59–85.02% (278/327), and aged 60 to 89–91.43% (96/105). Comparing the RNA testing rates and treatment rates before and after the new pattern, there were statistical differences ($p < 0.05$). Cases aged 90 and above had the RNA testing rate of 0. After the new pattern, the lost-to-follow-up cases still accounted for 18.67%, which may be one of the reasons affecting the treatment rate. After being followed up, a total of 302 HCV antibody positive cases agreed to get re-examined, of which 35 cases were RNA positive and 33 received treated. After complete treatments and re-examinations, the complete virological response rate was 100%.

Conclusion: The new management pattern of hepatitis C in hospital effectively reduced the missed diagnosis of hepatitis C and increased the treatment rate, which is worth popularizing.

THU-408

The prognostic influence of toll-like receptor 4 +3725G/C gene polymorphism on biochemical profile among chronic HCV hepatitis patients

Tetiana Bevz¹, Iryna Bondaruk¹, Kiarina Myroniuk-Konstantynovych¹, Larysa Moroz¹, Galyna Martyniuk², Yaroslav Demchysyn¹. ¹National Pirogov Memorial Medical University, Vinnytsia, Ukraine; ²Central city hospital, Rivne, Ukraine
Email: tasya241@gmail.com

Background and aims: The progression of chronic hepatitis C (CHC) and the development of liver fibrosis appear due to the multifaceted morphological response of the liver to hepatocyte damage. Therefore, the main task during choosing of management approaches of patients with CHC is to assess the degree of necro-inflammatory changes and the stage of liver fibrosis.

Method: We examined 131 patients with CHC (diagnosis confirmation by qualitative and quantitative HCV-RNA determination, HCV-genotyping), age 26–72 yrs (average age 43.8 ± 0.84 yrs). Among examined patients there were 59 females and 72 males.

Results: The ALT level of 116.72 ± 9.31 IU/l was determined in the carriers of the GC genotype, which was 1.79 fold higher ($p < 0.001$) than in the carriers of the GG genotype, and in monozygotic carriers of the C allele (CC-genotype) it was 2.57 fold higher ($p < 0.001$). The level of AST in serum of carriers of genotypes GC/CC was 77.09 ± 7.01 IU/l/100.46 ± 11.79 IU/l, vs. among GG genotype carriers–44.39 ± 2.49 IU/l ($p < 0.001$). LDH level was also significantly higher in patients with the C allele of the TLR4 gene ($p < 0.05$). The level of total bilirubin in carriers of the GC and CC genotypes were 1.55 and 1.68 fold higher ($p < 0.001$), accordingly, than among individuals with the GG genotype. The level of GGT in the CC genotype patients was higher ($p < 0.001$) than in individuals with the GG genotype: 155.53 ± 18.38 IU/l vs. 57.56 ± 3.67 IU/l. The presence of the C allele reliably affected the reduction of total protein and albumin levels. Cholesterol level in patients with genotypes GC and CC was higher in 1.22 fold ($p < 0.001$) than in patients with genotype GG. The assessment of the direction, strength and reliability of correlation relations between CC/GC genotypes of the TLR4 gene and indexes of the functional condition of the liver in patients with CHC had shown a direct correlation of significant strength in the presence of the C allele with the level of ALT ($r = 0.52$; $p < 0.05$) and the level of total bilirubin ($r = 0.56$; $p < 0.05$), a direct correlation of moderate strength with the level of AST ($r = 0.44$; $p < 0.05$), GGT ($r = 0.48$; $p < 0.05$) and cholesterol ($r = 0.44$; $p < 0.05$), moderate strength inverse correlation with the level of total protein ($r = -0.34$; $p < 0.05$) and albumin level ($r = -0.51$; $p < 0.05$). ALT (beta = 0.38; $p = 0.004$), albumin level (beta = -0.2; $p = 0.009$) and total bilirubin (beta = 0.32; $p = 0.0001$) as independent clinical predictors by means of multivariate analysis and a logistic regression model. The factor logistic model was reliable with the coefficient of determination of 52%.

Conclusion: Carriers with CC and GC genotypes of the TLR4 gene rs11536889 +3725G/C have a significantly more severe course of CHC than GG genotype carriers that is showed by the main cytolytic, cholestatic and hepatocellular insufficiency syndromes indexes.

THU-410

Clinical interventions and use of resources for the management of adverse effects associated with multiple drug interactions in the hepatitis C population

Juan Turnes¹, Antonio Garcia Herola², Ramón Morillo Verdugo³, Marinela Mendez⁴, Candido Hernández⁵, Antoni Sicras Mainar⁶. ¹Servicio de Gastroenterología y Hepatología, CHU, Pontevedra, Spain; ²Sección de Medicina Digestiva. Hospital Marina Baixa de Villajoyosa, Alicante, Spain; ³Farmacia Hospitalaria, Hospital de Valme, AGS Sur de Sevilla, Sevilla, Spain; ⁴Medical Affairs, Gilead Sciences S.L., Madrid, Spain, Madrid, Spain; ⁵Medical Affairs, Gilead Sciences S.L., Madrid, Spain; ⁶Health Economics and Outcomes Research, Atrys Health, Barcelona, Spain
Email: jturnesv@gmail.com

Background and aims: Direct-acting antivirals (DAAs) share pharmacokinetic pathways with many comedications commonly administered to patients living with chronic hepatitis C virus (HCV) infection (PLWHCV). Previous studies have analyzed prevalence of potential drug-drug interactions (DDIs) between comedication taken by PLWHC and DAAs, including single and multiple-DDIs (≥2 drug-drug interactions with DAAs) and reported adverse effects (AEs) associated to DDIs. This study aims to evaluate the clinical interventions and resources utilization to manage AEs in patients with multiple-DDIs and the medical specialties that reported AEs.

Method: retrospective observational study, obtained from the BIG-PAC database (Atrys Health), in HCV patients (2017–2020). Potential DDIs treated with DAAs (Sofosbuvir/Velpatasvir [SOF/VEL] and Glecaprevir/Pibrentasvir [GLE/PIB]) were evaluated using the University of Liverpool DDIs database. The AEs, clinical interventions, use of resources for the management of AEs and the specialty that reported AEs were analyzed.

Results: 1620 patients were included (730 treated with SOF/VEL and 890 with GLE/PIB). 27.4% (444/1620) of the total patients who received comedications showed at least ≥1 Potential DDI. About 10% (123/1256) of patients receiving ≥2 comedications had potential multiple-DDIs (52 with SOF/VEL and 71 with GLE/PIB). 18 AEs were reported, of which 16 occurred in patients with potential multiple-DDIs. Therefore, 13% (16/123) of patients with potential multiple-DDIs presented AEs. All AEs required clinical interventions or use of resources for their management. The most frequent interventions were discontinuations (of comedication or DAAs) and reduction of comedication dose, being more frequent in the group treated with GLE/PIB, since this group presented approximately three times more AEs than the group treated with SOF/VEL (18.3% GLE/PIB [13/71] vs 5.8% SOF/VEL [3/52]; $p < 0.05$). There were three DAAs discontinuations in patients treated with GLE/PIB (two associated with atorvastatin and one with quetiapine) and one in the group treated with SOF/VEL (associated with carvedilol). All dose reductions were reported in the group treated with GLE/PIB (associated with paliperidone, enalapril and simvastatin). AEs were reported mostly by primary care physicians (62.5%).

Conclusion: There is an elevated risk of AEs in hepatitis C patients with potential multiple-DDIs treated with DAAs, particularly with cardiovascular and nervous system comedication, especially with DAAs containing protease inhibitor. These AEs may require clinical interventions and the use of resources for their clinical management. This circumstance is especially relevant in the context of treatment simplification, where HCV specialists usually see the patients only at treatment initiation.

THU-411

Long term liver-related events in patients with HCV-related liver disease and advanced fibrosis after sustained virological response with direct-acting antivirals

Jorge Barajas¹, Tomás Artaza¹, Juan José Sánchez-Ruano¹, Marta Romero-Gutiérrez¹, Carolina Delgado¹, Gema De la Cruz¹, Concepción Gonzalez¹, Raquel Lomas¹, Rafael Gómez Rodríguez¹.
¹Complejo Hospitalario Universitario de Toledo, Toledo, Spain
Email: jorgebarper@gmail.com

Background and aims: Direct-acting antivirals (DAAs) achieve a high rate of sustained virological response (SVR) in patients with hepatitis C virus (HCV) infection. It is not clearly defined whether this SVR is associated with a reduction in liver-related events. We aim to analyze the development of complications related to portal hypertension (PH) as well as de novo hepatocellular carcinoma (HCC) in patients with SVR after DAAs treatment.

Method: An ambispective single-center study included 295 patients with SVR. Patients with HCV-related liver disease and advanced fibrosis treated with DAAs were included. Patients with transient elastography (TE) between 9.5 and 12.5 kPa were classified as F3, while those with TE >12.5 kPa or clinical, analytical, and ultrasound data compatible with cirrhosis were classified as F4. All patients achieved SVR, and consecutive sampling was performed from July 2014 to March 2022. Follow-up was censored at 5 years.

Results: The median age was 60 years and 185 (62.71%) were male. Two hundred thirty-two (78.64%) had cirrhosis. The mean follow-up was 47 months. Thirty-six (12, 2%) had a liver-related event. Complications related to PH were experienced by 20 (6.78%) patients during the first 5 years, all of them F4. Of the 20 patients with PH related complications, 17 (85%) had ascitic decompensation, 4 (20%) had gastrointestinal bleeding and 11 (55%) had hepatic encephalopathy. In our series, de novo HCC was developed by 22 (7.46%) patients. In 21 cases, HCC occurred in patients with F4. The median time to HCC diagnosis was 18 months (95% CI, 0.76–35.23). One patient treated with DAAs had a previous history of HCC and it did not recur. Thirty-four (11.52%) patients died at 5-years, with 12 (35.29%) dying from liver-related events. Among those deceased from liver-related events, 6 died from PH complications, 5 from HCC, and 1 patient died from cholangiocarcinoma. Four (1.36%) patients underwent liver transplantation, 2 for HCC and 2 for decompensated cirrhosis.

Conclusion: The risk of developing liver-related events in patients with advanced fibrosis due to HCV after SVR after DAAs treatment for the first 5 years was significant. In our series, 12.2% had a liver-related event. The most frequent events were the development of HCC (7.46%) and decompensation of liver disease (6.78%). Adequate follow-up in these patients appears crucial to achieve early management of these complications.

THU-412

Hepatitis C lost to follow-up rates in primary care practices in Belgium

Marie Coessens^{1,2}, Jeoffrey Schouten¹, Wim Verlinden^{1,2}.
¹Department of gastroenterology and hepatology, Vitaz, Sint-Niklaas, Belgium;
²Laboratory of Experimental Medicine and Pediatrics (LEMP), University of Antwerp, Wilrijk, Belgium
Email: wim.verlinden@vitaz.be

Background and aims: If we aim to eliminate hepatitis C (HCV) by 2030, resources need to be allocated efficiently. Belgian hospital-based lost to follow-up (LTFU) projects have shown that up to 19% of patients drop out of HCV care, with up to half of them being successfully re-admitted. This is the first project to assess LTFU rates in primary care, while promoting patient re-engagement in HCV care and the prevention of LTFU.

Method: A list was compiled by a non-hospital-based clinical laboratory, containing all positive HCV serology results requested between 2010 and 2023 by a general practitioner (GP) based in Antwerp. A member of the study team went through the patient list

together with the participating GPs, assessing patient status in the HCV care continuum [(a) negative HCV antibody confirmation test, (b) negative HCV antibody confirmation test and HCV RNA negative, (c) positive HCV serology and HCV RNA negative, (d) positive HCV serology without HCV RNA result available, (e) last available HCV RNA positive, (f) negative HCV RNA <12 weeks after end of treatment (EOT), (g) negative HCV RNA ≥ 12 weeks after end of treatment or sustained virological response (SVR), (h) deceased]. The patient was considered LTFU if no action was taken in case of status d, e, or f. GPs were encouraged to re-engage these patients in HCV care and LTFU rates were re-assessed after one year. A risk profile (age, gender, HCV genotype, presence of cirrhosis, HIV status, lifetime drug use, being born abroad) of patients with status e, f or g was developed to identify patients at risk of LTFU who need additional GP counselling for their referral to the hepatologist.

Results: In total, 167 out of 275 (60, 73%) GPs agreed to participate and 363 primary care patients were analysed for their status in the HCV care continuum [(a) 30/363 (8.26%); (b) 63/363 (17.36%); (c) 82/363 (22.59%); (d) 18/363 (4.96%); (e) 32/363 (8.82%); (f) 5/363 (1.38%); (g) 117/366 (32.23%); (h) 16/363 (4.41%)]. The rate of LTFU was 15.51% (55 out of 363). In addition, a liver-related cause of death was documented in 25% of deceased patients. For 9 patients that were initially considered LTFU [(d) 1/9; (e) 5/9; (f) 3/9], status in the HCV care continuum was already re-assessed one year after the project was launched [(e) 3/9; (f) 4/9; (g) 2/9]. Thanks to our intervention, DAA therapy was initiated in 3 out of 5 patients with an untreated chronic HCV infection and an SVR12 was already documented in 2 out of 9 patients. None of the risk factors for LTFU could be retained.

Conclusion: Hepatitis C LTFU rates in primary care are significant and up to half of patients can be successfully re-admitted to care. Given that the LTFU strategy comes without screening costs, this is a feasible and highly cost-effective strategy on the road towards HCV elimination.

 Email: yuki.tahata@gh.med.osaka-u.ac.jp

Background and aims: Direct-acting antiviral (DAA) therapy has enabled viral elimination in almost all cirrhotic patients with hepatitis C virus (HCV). Although some cirrhotic patients undergo aggravation of esophagogastric varix after DAA therapy, the factors associated with aggravation of esophagogastric varix in cirrhotic patients, including decompensated cirrhosis, are unclear.

Method: A total of 478 patients with HCV-related compensated or decompensated cirrhosis were treated with DAA between February 2019 and December 2021 at 31 Japanese hospitals. Among them, 207 patients who could evaluate esophagogastric varix before and after DAA therapy were enrolled in this study. Decompensated cirrhosis was defined as baseline Child-Pugh class B (CP-B) or C, or CP-A with decompensating events before DAA therapy. Sustained virologic response (SVR) was defined as serum HCV-RNA undetectable at 12 or 24 weeks after the end of treatment. The form of esophagogastric varix was evaluated according to Japanese general rules: F1 was straight, small-caliber one; F2 was moderately enlarged, beady one; and F3 was markedly enlarged, nodular or tumor-shaped one (Dig Endosc 2010;22:1–9). Patients without esophagogastric varix or those with F1 were defined as low-risk varix, and patients with F2 or more or with a history of varix rupture were defined as high-risk varix. Aggravation of esophagogastric varix was defined as varix rupture or treatment for varix. We examined the cumulative incidence rate and the factors associated with aggravation of esophagogastric varix after DAA therapy.

Results: The median age was 69 years old, 55% of patients were male, 60% were decompensated cirrhosis, and 28% had high-risk varix at baseline. SVR rates of patients with compensated and decompensated cirrhosis were 98.8% and 96.0%, respectively ($p = 0.228$). During the median observation period of 39.2 months from starting DAA therapy, 22 patients underwent treatment for varix, and three experienced varix rupture. The 3-year rate of aggravation of esophagogastric varix was 11.5%. In multivariate Cox proportional hazard analyses, high-risk varix at baseline ($p < 0.001$), baseline higher gamma-glutamyl transpeptidase (GGT) levels ($p = 0.003$), and virologic response ($p = 0.045$) were significantly associated with aggravation of esophagogastric varix, while alcohol consumption was not. The 3-year rates of aggravation of esophagogastric varix were 27.5% in patients with high-risk varix, 5.9% in those with low-risk

varix, and 23.8% in patients with GGT of 75U/l or more and 8.2% in those with GGT less than 75U/l, respectively.

Conclusion: In cirrhotic patients with HCV treated with DAA, baseline status of esophagogastric varix, baseline GGT levels, and virologic response to DAA were significantly associated with the aggravation of esophagogastric varix.

THU-414

Incidence of hepatocellular carcinoma in patients with hepatitis C treated with direct-acting antiviral agents: results of a long-term prospective study period

Emanuela De Santis¹, Alessandro Caioli¹, Fernando De Angelis¹, Adriano De Santis¹. ¹Sapienza, University of Rome, Rome, Italy
 Email: emanuela.desantis@uniroma1.it

Background and aims: Hepatocellular carcinoma (HCC) is the most common primary liver tumor. Liver cirrhosis, whose one of the main etiological agents is hepatitis C virus (HCV) infection, represents the most frequent risk factor. Direct-acting antivirals (DAAs) are associated with a sustained virological response (SVR) rate of more than 95%. Despite viral eradication, however, a residual risk of HCC persists in patients with significant fibrosis, especially in cases with concomitant liver-related comorbidities. Several works in the literature have investigated the incidence of HCC after SVR from DAAs. However, in published cases the follow-up is limited to 3 years. This work aims to evaluate the incidence of HCC in patients with hepatitis C who have achieved SVR after being treated with DAAs considering a follow-up time beyond the three years considered in the literature, and to identify predictive factors for development of hepatocellular carcinoma.

Method: We have examined 452 patients suffering from HCV-related chronic hepatitis and undergoing treatment with DAAs. Anthropometric, anamnestic, laboratory, ultrasound and elastography data have been collected for each patient at three times: T0 (before starting antiviral therapy), T1 (6 months after the end of treatment), T2 (last clinical data relating to the last follow-up visit/date of HCC diagnosis). The total duration of the follow-up has been calculated in all patients.

Results: In our sample, 18 patients (4%) developed hepatocellular carcinoma: 11 (61.1%) had a diagnosis of liver cirrhosis confirmed using elastography and biochemical data, while for the remaining 7 (38.9%), the fibrosis was classified as absent or minimal. A Cox regression model was used to identify predictive factors for the onset of HCC. Variables that were found to be significantly positively associated with the onset of HCC in simple and multiple regression were: AFP levels at T0, APRI levels at T0 and male sex. For the 7 patients in which significant fibrosis had been excluded, histological examination of liver tissue resulted in a diagnosis of liver cirrhosis. In 4 of these individuals, the identification of hepatocarcinoma occurred 5 years after the start of antiviral therapy and in 1 subject more than 7 years later.

Conclusion: In conclusion, in our sample, for 38.8% of the HCC cases the fibrosis stage was underestimated, resulting in the exclusion of these patients from follow-up. Our study demonstrates that AFP and APRI levels at baseline could be useful for selecting patients for whom it is appropriate to continue follow-up despite the absence of significant fibrosis.

Email: mvergara@tauli.cat

Background and aims: Since the introduction of direct-acting antivirals for the treatment of chronic hepatitis C, the majority of patients have been treated and cured of the infection. However, the remain undetected patients are crucial to be promptly treated to achieve virtual elimination of the virus by 2030. In Spain, screening is not universal and depends on clinical suspicion based on clinical history. Recent published results on emergency screening near our area reflected bimodal distribution of RNA-VHC in our population: men between 50–60 years old and women under 90. We performed automated screening for hepatitis C antibodies (HCV-Ab) in patients over 50 who were undergoing preoperative analysis for elective surgery, both outpatient and inpatient.

Method: All patients over fifty years' old who underwent preoperative analysis were studied with a HCV-Ab detection in the same blood sample as required by the anaesthetists before surgery. Those who were positive, HCV-RNA was determined with the same sample. If a positive value was confirmed, they were referred to the Hepatology Unit for evaluation and treatment through an alert issued from the laboratory directly to the Unit.

Results: Preliminary results obtained from September 1 to December 31, 2023, a total of 2, 121 patients were evaluated. Forty-five (2.1%) were positive for HCV-Ab, of which 4 (0.18%) were positive for HCV-RNA. Two of them were men aged 54 and 55, one of them with cirrhosis criteria by transitional elastography (17.4 Kpa (IQR med 8%). The patients were not previous aware of de HCV infection. Both patients were treated with direct antiviral agents achieving a sustained virological response without any side effects. The other two were 83 and 89 old women respectively without any signs of significant fibrosis neither analytical, echography or elastography criteria (6, 6 and 7.1 KPa respectively), that denied treatment.

Conclusion: Automated preoperative screening in patients over 50 years old makes it possible to detect patients with HCV-RNA not aware of the infection helping to eradicate the virus. Cost effectiveness study of this strategy is pending but the low cost of VHC-Ab and the QALY gained make its effectiveness highly probable.

Regression of hepatic fibrosis in patients with chronic hepatitis C treated with direct-acting antivirals (DAAs). A long-term, prospective, observational study

Evdoxia Avramopoulou¹, Efthymios Tsounis¹, Stavros Kanaloupitis¹, Konstantinos Zisimopoulos¹, Maria Kalafateli^{2,3}, Ioanna Aggeletopoulou¹, Christos Sotiropoulos⁴, Theodora Kafentzi⁴, Georgios Geramoutsos¹, Odysseas Ampazis¹, Georgia Diamantopoulou¹, Angeliki Tsintoni⁵, Konstantinos Thomopoulos¹, Christos Triantos¹. ¹Division of Gastroenterology, Department of Internal Medicine, University Hospital of Patras, Patras, Greece; ²Department of Gastroenterology, General Hospital of Patras, Patras, Greece; ³Patras General Hospital "Agios Andreas", Gastroenterology, Patra, Greece; ⁴Division of Gastroenterology, Department of Internal Medicine, University Hospital of Patras, Patras, Greece; ⁵Department of Internal Medicine, University Hospital of Patras, Patras, Greece
Email: chtriantos@hotmail.com

Background and aims: Successful hepatitis C virus (HCV) treatment with direct-acting antivirals (DAAs) is associated with an improvement in liver fibrosis post-treatment. This study aims to assess the

long-term impact of DAA-based therapy on hepatic fibrosis through extended follow-up (FUP).

Method: Successful HCV treatment with DAAs is associated with an improvement in liver fibrosis post-treatment. This study aims to assess the long-term impact of DAA-based therapy on hepatic fibrosis through extended FUP.

Results: The overall sustained virologic response rate for this cohort was 98.8% (166/168). The median liver stiffness before treatment was 9.9 kPa (IQR: 7.5–18.8) compared to 7.2 kPa (IQR: 5.1–11.6) following DAA-based therapy ($p < 0.001$). In non-cirrhotic patients, the median transient elastography measurements were significantly reduced ($p < 0.001$) from 7.6 kPa (IQR: 6.5–9.2) to 5.8 kPa (IQR: 4.5–7.3). In patients with cirrhosis, the median liver stiffness plummeted from 18.6 kPa (IQR: 12.4–23.7) to 11.6 kPa (IQR: 7.3–17.2) after a FUP period of 31 months (IQR: 12–63.5) ($p < 0.001$). Regression of significant fibrosis (F4 stage) was observed in 18/36 patients (50%) using a cut-off value of 12 kPa. Moreover, the median Child-Pugh (CP) score was decreased from 7 (IQR: 5–7) to 5 (IQR: 5–7) post-treatment ($p = 0.002$). Nine out of 21 (42.9%) patients with baseline Child Pugh (CP) stage B regressed to CP stage A. Regression of liver fibrosis was also evident in various sub-group analyses, including patients with diabetes mellitus [baseline 15.5 kPa (IQR: 10.3–19.1) vs FUP 8.1 kPa (IQR: 5.7–9.9); $p = 0.12$], current intravenous drug user (baseline 9.7 kPa (IQR: 6.2–13.2) vs FUP 6.7 kPa (IQR: 5.2–9.2); $p = 0.049$], and alcohol-abuse [baseline 12 kPa (IQR: 7.7–20.4) vs FUP 7.7 kPa (IQR: 5.4–12); $p < 0.001$].

Conclusion: The current analysis supports a substantial improvement in hepatic fibrosis in HCV across diverse subgroups of HCV patients who received DAA-based treatment during long-term FUP. In cirrhotic patients, treatment with DAAs could lead to cirrhosis regression.

THU-420

Evaluation of LiverRisk score as predictor of liver fibrosis and mortality in patients with HCV-related hepatitis treated with direct acting antivirals

Antonietta Romano¹, Amalia Rita Caspanello^{1,2}, Salvatore Piano¹, Marta Tonon¹, Carmine Gambino¹, Valeria Calvino¹, Anna Barone¹, Nicola Zeni¹, Simone Incicco³, Roberta Gagliardi¹, Paolo Angeli¹. ¹Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padova, Italy, Padova, Italy; ²Department of Clinical and Experimental Medicine, Unit of Medicine and Hepatology, University of Messina, Messina, Italy; ³Unit of Internal Medicine and Hepatology, Department of Medicine, University of Padova, Italy, Padova
Email: antonietta.romano@aopd.veneto.it

Background and aims: The LiverRisk score has been recently developed and validated as a predictor of liver fibrosis and liver-related outcomes in the general population. This score has never been evaluated as predictor of liver fibrosis and outcomes in secondary care, such as in patients with chronic liver diseases. The aim of this study was to evaluate the role of the LiverRisk score as a predictor of liver fibrosis and mortality in patients with HCV-related hepatitis treated with direct acting antivirals (DAA).

Method: patients were enrolled retrospectively, outpatients with chronic hepatitis C treated with DAA between 2015 and 2017 were included consecutively. Patients were followed-up until September 2023. The exclusion criteria were: liver transplantation before DAAs and presence of HCC. Patient characteristics and LiverRisk score were collected before starting the DAA. The data for the calculation of LiverRisk score were collected the same day the fibroscan was performed. The primary end point was a liver stiffness ≥ 10 kPa. Area under the receiver operating characteristic (AUROC) curve was evaluated for assessing the discrimination ability of Liver Risk score. Overall mortality was assessed at the end of follow-up.

Results: in this ongoing study, 136 patients of our center with chronic hepatitis C treated with DAA were enrolled. In this population, 51% were men, the mean age was 65.3 ± 12.2 years, 65.4% were genotype

1, 59.6% had liver cirrhosis, the mean liver stiffness measurement was 15.9 KPa (3.5–48.8), sustained virological response (SVR) was 95.5% and the mean follow-up was of 59 months. Coinfection with hepatitis B virus (HBV) was present in 8.8%. Discrimination ability of the LiverRisk score in the prediction of liver stiffness ≥ 10 KPa was very good as shown by an AUROC of 0.848 (95% confidence interval [CI] = 0.767–0.930; $p = 0.000$). During follow-up 21 patients (15.4%) died. LiverRisk score was associated with the risk of all cause of mortality (Hazard Ratio = 1.154; 95% CI = 1.01–1.318; $p = 0.035$).

Conclusion: the liver risk score is a good predictor of fibrosis and mortality in HCV patients treated with DAA.

Viral hepatitis C – Therapy and resistance

THU-362

Ravidasvir in combination with sofosbuvir for 12 or 24 weeks achieved high sustained virological response rates in genotype 3 chronic hepatitis C without or with compensated liver cirrhosis

Soek Siam Tan¹, Caroline Men  trez², Isabela Ribeiro², Nicolas Salvadori³, Sabine Yerly⁴, Nicole Ngo-Giang-Huong⁵, Graciela Diap². ¹Hospital Selayang, Dept of Hepatology, Batu Caves, Malaysia; ²DNDi, Geneva, Switzerland; ³AMS-PHPT Research Platform, Muang, Chiang Mai, Thailand; ⁴Hopitaux Universitaires de Gen  ve, Gen  ve, Switzerland; ⁵AMS-BAT Laboratory, Muang, Chiang Mai, Thailand
Email: tanss@selayanghospital.gov.my

Background and aims: Hepatitis C virus (HCV) genotype (GT) 3 is the second most common GT and accounts for approximately 14–17 million of the estimated 58 million HCV cases globally. GT3 is associated with injecting drug use (IDU), the primary mode of HCV transmission, with more severe liver disease and a lower sustained virological response (SVR), especially in patients with cirrhosis, even in the era of direct-acting antiviral therapies. Ravidasvir, a potent NS5A inhibitor with no clinically significant interaction with cytochrome P450 enzymes, was recently added to the WHO Model Lists of Essential Medicines for the treatment of HCV in combination with sofosbuvir, based on the results of the phase 2/3 STORM-C-1 trial. We analysed the GT3 cohort of this trial to report on efficacy in this subpopulation.

Method: An open-label, single-arm phase 2/3 study in people with chronic HCV \pm HIV infections of all GT was conducted in Malaysia and Thailand. Ravidasvir (200 mg) and sofosbuvir (400 mg) were administered once-daily for 12 weeks to patients without cirrhosis and for 24 weeks to those with compensated cirrhosis (CC). The primary efficacy end point was SVR at 12 weeks post-treatment. Patients underwent clinical and laboratory assessments at weeks 1 and 4 and then every 4 weeks during treatment and at 4, 12 and 24 weeks post-treatment.

Results: Of the 603 patients enrolled, 296 (49%) had HCV GT3; of these, 258 (87%) had subtype 3a, 34 (11%) had subtype 3b, and 4 (1%) could not be subtyped. The median age was 48 years (IQR 41–56), 77% were male, 53% had cirrhosis, 23% were interferon \pm ribavirin treatment-experienced, and 49% reported a history of IDU. SVR at 12 and 24 weeks post-treatment (SVR12/24) was 97.6% (289/296), with similar rates between those without cirrhosis, 97.8% (136/139) and those with CC, 97.5% (153/157). The SVR 12/24 for GT3a was 98.1% (253/258) and for GT3b was 97.1% (33/34). In patients with any baseline resistance-associated substitution (RAS), the SVR12/24 was 96.7% (59/61) in GT3a and 97.1% (33/34) in GT3b. Of the 41 patients with GT3a and baseline Y93H RAS, 39 (95.1%) achieved SVR12/24, including all 9 patients with both S62L and Y93H RAS. Three patients

who did not achieve SVR12/SVR24 discontinued treatment early after 2, 3 and 9 doses of study drugs. Virological failure was observed in four of 296 (1.4%) patients. Three had baseline RAS, 93H ($n = 2$) and 30 K + 31 M ($n = 1$), but none had treatment-emergent RAS in NS5A or NS5B. One patient had no baseline RAS results as amplification was not possible.

Conclusion: In chronic GT3 hepatitis C, the combination of ravidasvir and sofosbuvir for 12 weeks in patients without cirrhosis and 24 weeks in patients with CC achieved high SVR12/24 of 97.8% and 97.5%, respectively. There was a minimal impact of the presence of Y93H RAS at baseline on response rates and no evidence of treatment-emergent virologic resistance.

THU-363

Validation of a modified pediatric formulation of Sofosbuvir and Daclatasvir in genotype-4 HCV-infected children weighing 17–35 Kg

Email: manalhelsayed@yahoo.co.uk

Background and aims: Sofosbuvir (SOF) plus Daclatasvir (DCV) is the regimen of choice in low and middle-income countries (LMICs) for treatment of chronic hepatitis C virus (HCV) infection in adults and adolescents. Based on extrapolation of efficacy, safety and PK data from studies in adults, adolescents or older children and PK simulation studies, in 2022 the World Health Organization (WHO) recommended this regimen to older children (6–11 years and weighing >26 kg) at adult dose (400/60 mg) and in younger children 3–5 years or weighing 14–25 kg at half the adult dose (ie 200/30 mg). However, clinical data on this dose in younger children is still lacking. We conducted a clinical pharmacokinetic study to assess the pharmacokinetics, safety, efficacy, and acceptability of once daily 30 mg DCV plus 200 mg SOF for 12 weeks in treatment-na  ve children weighing 17 to ≤ 35 kg with chronic HCV infection.

Method: This study is an interventional, single centre, single arm, open label clinical trial that included treatment-na  ve children with chronic HCV infection of median age 7 years (range 5–13 years) and weight 17 to ≤ 35 kg. Children who weighed 17 to ≤ 35 kg received once daily oral DCV 30 mg in combination with 200 mg SOF (two small 100 mg tablets new formulation) for 12 weeks. A swallow-ability test was performed before inclusion in the trial. Steady state plasma concentrations were determined. Non-compartmental PK analysis was performed using Pkanalix 2023. Efficacy was assessed using quantitative HCV-PCR at the end of treatment (EOT) and 12 weeks after finishing treatment (SVR12). Patients were followed up for any adverse events. Palatability of the tablets was recorded at each study visit. The study is registered at ClinicalTrials.gov under NCT05854511.

Results: Twelve patients weighing 17 ≤ 35 kg were included. All patients (12/12) completed the 12 weeks course of SOF + DCV. Mean \pm standard deviation for the area under the curve (AUC)₂₄, maximum plasma concentration at steady-state (C_{ssmax}), and minimum plasma concentration at steady-state (C_{ssmin}) were: 11, 082 \pm 5, 168 h-ng-ml⁻¹, 1, 062 \pm 342 ng-ml⁻¹ and 198 \pm 156 ng-ml⁻¹, respectively for DCV; 2, 127 \pm 1, 866 h-ng-ml⁻¹, 952 \pm 579 ng-ml⁻¹ and 18 \pm 21 ng-ml⁻¹, respectively for SOF; 15, 256 \pm 4, 113 h-ng-ml⁻¹, 1605 \pm

POSTER PRESENTATIONS

743 ng·ml⁻¹ and 312 ± 112 ng·ml⁻¹, respectively for its major metabolite GS331007. Results for DCV values are comparable to those achieved by adults. All patients (12/12) achieved SVR12. No serious adverse events were reported. All patients (12/12) could swallow the medication with no difficulty.

Conclusion: A combination of half of the available adult SOF/DAC dose, 30 mg DCV and 200 mg SOF, provides safe and effective drug exposure, and is well-tolerated orally in children weighing 17–35 Kg. This preparation can provide an affordable formulation for treatment of chronic hepatitis C infection in young children to scale up elimination in this special population.

THU-364

Modeling suggests that undetectable HCV at week 2 of DAA therapy could identify patients for shorter treatment duration

Ashish Goyal¹, Ohad Etzion², Kimberly Page³, Tatyana Kushner⁴, Yedidya Saiman⁵, Scott Cotler¹, Harel Dahari¹. ¹Program for Experimental and Theoretical Modeling, Division of Hepatology, Department of Medicine, Stritch School of Medicine, Loyola University Chicago, Maywood, IL, United States; ²Soroka University Medical Center, Beersheva, Israel; ³Division of Epidemiology, Biostatistics and Preventive Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States; ⁴Division of Liver Diseases, Icahn School of Medicine at Mount Sinai, New York, NY, United States; ⁵Department of Medicine, Section of Hepatology, Lewis Katz School of Medicine at Temple University, Temple University Hospital, Philadelphia, PA, United States
Email: harel.dahari@gmail.com

Background and aims: The World Health Organization (WHO) calls for identifying predictors of successful treatment with reduced duration of DAA therapy. This objective is particularly important in people who inject drugs (PWID), in whom shorter treatment could improve adherence, decrease loss to follow-up, and reduce cost. In addition, there is a need to minimize DAA duration to reduce DAA exposure and increase acceptance in pregnant women. Here we investigate the feasibility of response-guided therapy (RGT) to reduce length of treatment using a computational modeling approach.

Method: Previous modeling efforts based on ~300 patients receiving DAA (such as sofosbuvir + velpatasvir, elbasvir + grazoprevir, sofosbuvir + ledipasvir, or pibrentasvir + glecaprevir) allowed us to characterize viral-host parameters, DAA efficacy in blocking HCV production, and treatment outcomes [Math Biosci. 2022 Jan;343:108756]. Based on this real-life patient data, parameter distributions were identified and then 20,000 parameter combinations of viral-host and treatment parameters were generated, each representing an *in silico* patient. Next, viral kinetic profile under DAA treatment for each patient was simulated using a multiscale model [Proc Natl Acad Sci U S A. 2013 Mar 5;110 (10):3991–6]. The time to cure (TTC) for each *in silico* patient, defined as the time to reach less than one HCV viral copy in the 15L of extracellular body fluid, i.e. $V = 7 \times 10^{-5}$ IU/ml [Sci Rep. 2020 Oct 20;10 (1):17820], was then estimated using mathematical modeling simulations.

Results: Out of 20,000 *in silico* patients, about 10,000 (~50%) achieved undetectable HCV (<1 IU/ml) by day 14 after initiation of treatment. Modeling suggests that if HCV is undetectable on or before day 14 of DAA therapy, 90% and 98% of HCV-infected individuals can be cured within 4 and 5 weeks of DAA treatment, respectively. The median predicted TTC was ~22 days with ~0.6% reaching TTC as early as 2 weeks. Approximately 8% of these cases also had undetectable viral load at day 7, predicting that 90% and 98% cure rates could be achieved with 3 and 4 weeks of DAA treatment, respectively.

Conclusion: Mathematical modeling of *in silico* patients that reach undetectable HCV by day 14 predicted that >90% cure rates could be achieved with 4–5 weeks of DAA therapy. This RGT could improve treatment access, facilitate HCV elimination, and reduce cost, particularly in patient groups most affected by HCV such as PWID.

Email: fish6069@gmail.com

Background and aims: The once-daily, oral, fixed-dose, direct-acting antiviral combination of glecaprevir/pibrentasvir (G/P) is indicated for chronic hepatitis C (CHC) infection with HCV genotypes 1–6 in patients with or without compensated cirrhosis (CC). Treatment duration of 8 weeks is recommended in all treatment-naïve (TN) patients. As Taiwan government is committed to eliminating HCV by 2025, this study aimed to measure the real-world evidence for TN patients using 8-week G/P in Taiwan HCV Registry (TACR).

Method: The TACR is an ongoing nationwide registry program organized and supervised by Taiwan Association for the Study of the Liver (TASL), which aims to setup a database and biobank of patients with CHC in Taiwan. Data was analyzed as of 31 May 2023 for CHC patients treated with G/P. Effectiveness reported as sustained virologic response at post-treatment week 12 (SVR12) was assessed by modified intent-to-treat (mITT) populations that excluded patients who lost to follow-up or without SVR12 data. Safety profile was assessed in the ITT population.

Results: Of 8,041 TN patients treated with G/P, 7,246 patients received 8-week regimen (ITT) and 7,204 of which had SVR12 data available (mITT). The overall SVR12 rate was 98.9% (7,122/7,204) in the mITT population. For selected subgroups including patients with compensated cirrhosis, GT3, diabetes, chronic kidney disease, person who inject drugs, and HIV, the SVR12 rate was 98.3% (342/348), 95.1% (272/286), 98.9% (1,084/1,096), 99.0% (1,171/1,183), 97.4% (566/581), and 96.1% (248/258), respectively. Overall, 14.1% (1,021/7,246) of the patients experienced adverse events (AEs) in the ITT population. Twenty-two patients (0.3%) experienced serious adverse events and

fifteen (0.2%) resulted in permanent drug discontinuation. None of them were considered as treatment drug related. The most frequent AEs (>5%) were fatigue (5.6%) and pruritus (5.4%). Laboratory abnormalities of Grade 3 and 4 for bilirubin, AST, and ALT were all 0.2%, respectively.

Conclusion: In this real-world Taiwanese cohort, 8-week G/P therapy was effective and well-tolerated in all TN patients, including general and special populations.

THU-366

Use of proton pump inhibitors among German Hepatitis C patients treated with sofosbuvir/velpatasvir: Data from the German Hepatitis C-Registry (2016–2022)

Markus Cornberg¹, Gerlinde Teuber², Ralf Link³, Uwe Naumann⁴, Hartwig Klinker⁵, Christine John⁶, Candido Hernández^{7,8}, Marianna Schwenken⁹, Christoph Sarrazin¹⁰. ¹Hannover Medical School, Hannover, Germany; ²Private Practice, Frankfurt/Main, Frankfurt am Main, Germany; ³MVZ-Offenburg GmbH, Offenburg, Germany; ⁴UBN/Praxis, Berlin, Germany; ⁵University of Würzburg Medical Center, Würzburg, Germany; ⁶Private Practice of Internal Medicine, Center of Gastroenterology, Berlin, Germany; ⁷Gilead Sciences Europe Ltd, Uxbridge, United Kingdom; ⁸Gilead Sciences, S.L, Madrid, Spain; ⁹Gilead Sciences GmbH, Munich, Germany; ¹⁰Department of Internal Medicine and Liver Center, Wiesbaden, Germany
Email: cornberg.markus@mh-hannover.de

Background and aims: Literature and product labels suggest velpatasvir bioavailability may be reduced when administered concomitantly with a proton pump inhibitor (PPI), based on pharmacokinetic studies. We aimed to determine the clinical relationship between PPI use and sustained virologic response rates (SVR) in patients treated with sofosbuvir/velpatasvir (SOF/VEL) ± ribavirin (RBV) in a real-world, ongoing, noninterventional, multicenter, prospective, observational German Hepatitis C-Registry (DHC-R). The DHC-R is a national multicenter real-world registry including about 18,900 patients.

Method: The present analysis is based on 1,154 patients enrolled between 2016 and 2022 in the DHC-R, as treated with SOF/VEL, split between those receiving and not receiving PPI drugs as comedication. Baseline characteristics (demographics, viral infection, liver status, number and type of PPI drugs) and SVR (patients with SVR available: based on modified intention to treat (mITT), including patients with ITT SVR and ITT relapses) were analyzed. Also, co-use of metamizole was collected, as this comedication shows the same drug-drug interaction (DDI) profile as PPIs (risk of direct acting antiviral (DAA) exposure), thus checking a multi-drug-drug interaction (DDI) scenario.

Results: Patients receiving PPI represented 8.5% (98/1,154) of the total SOF/VEL cohort. Pantoprazole was the most common PPI co-used (78/98 patients; dose per day: 20 mg: 28/78, 40 mg: 29/78, 80 mg: 2/78, unspecified: 19/78 patients), followed by omeprazole (19/98 patients; dose per day: 20 mg: 14/19, 40 mg: 2/19, unspecified: 3/19 patients) and esomeprazole (1/98 patients; dose per day: 80 mg: 1/1), with 9.2% of the SOF/VEL+ PPI group also receiving metamizole. Those patients receiving PPI vs. non-PPI seemed older (≥50 years old (yo): 59% and 37%, respectively), with more females (38% and 27%), less genotype 3 (GT3) (47% and 62%), but with a higher proportion of cirrhosis (compensated cirrhosis (CC): 50% and 32%; decompensated cirrhosis (DC): 17% and 4%). In terms of effectiveness, SVR was similar in both groups, also in cirrhosis (=98%) for all genotypes, and even in the presence of GT3 + CC (both ≥96%). Co-use of metamizole had no impact on SVR (=100%). Besides, no negative PPI dose-dependent SVR trend was noticed with the PPI dose given (20 mg: =96–100%, 40 mg: =91–100%, 80 mg: =100%, unspecified dose: =100%).

Conclusion: PPI co-use in patients under SOF/VEL therapy included in DHC-R did not impact the SVR. Those results were also not impacted by the cirrhotic status, PPI dose or the presence of a multi-DDI scenario.

Email: michal.brzdek@gmail.com

Background and aims: In the interferon (IFN) era, therapeutic options and their efficacy in treating chronic hepatitis C virus (HCV) infection in elderly patients were severely limited. The introduction of direct-acting antivirals (DAAs) with their effectiveness and safety has revolutionized the approach to treating this population. Nevertheless, elderly patients have often been excluded from participation in clinical trials of DAA drugs, so the results of real-world studies are particularly important in the context of the geriatric population. The current study was conducted among patients over the age of 65, with notable inclusion of those over the age of 85. The study aims to analyze the effectiveness and safety of antiviral DAA treatment in an elderly HCV-infected population.

Method: All consecutive patients aged 65 and above selected from 16, 828 individuals with chronic HCV infection from the EpiTer-2 multicenter database were included in the study. The analyzed patients were divided by age into three groups: Group A (65–74 years), Group B (75–84 years) and Group C (85 years or older). Patients started IFN-free therapy at 22 Polish hepatology centers between July 2015 and December 2022. Treatment effectiveness was assessed by sustained virologic response (SVR). Safety data were collected during therapy and at 12-week follow-up.

Results: A total of 3, 505 elderly patients were included in the analysis, and they were divided into three groups: 2, 501 patients in Group A, 893 in Group B, and 111 in Group C. The studied population, regardless of age group, was predominantly female. Patients had a high prevalence of comorbidities (84.9%, 92.2%, and 93.7%, respectively) as well as a high rate of using concomitant medications. In the per-protocol (PP) analysis, both Groups A and B achieved a similarly high SVR rate of up to 97.9%, and in all patients aged 85 and older SVR was documented. Similarly, high SVR rates exceeding 94% were documented in subgroups based on gender, fibrosis severity, HCV genotype, and prior treatment history.

Conclusion: IFN-free therapies are highly effective and well tolerated by the elderly, including those over 85 years. Age should not be a barrier to treatment, but careful management is necessary.

THU-370

Hepatocellular carcinoma may be a viral reservoir during treatment of hepatitis C with direct-acting antivirals

Mário Jorge Silva^{1,2,3}, Ana Patricia Negrinho², Fatima Oliveira Martins², Antonio Figueiredo^{1,3}, Helena Gloria^{1,3}, Carina Santos^{1,3}, Pedro Lages Martins^{1,2,3}, Vasco Ribeiro^{1,2,3}, Mario Oliveira^{1,3}, Hugo Pinto Marques^{1,2,3}, Silvia Vilares Conde², Filipe Calinas^{1,3}. ¹Centro Clínico Académico de Lisboa, Lisbon, Portugal; ²NOVA Medical School, Lisbon, Portugal; ³Centro Hospitalar Universitário de Lisboa Central/Unidade Local de Saúde São José, Lisbon, Portugal
Email: mariojorgesilva01@gmail.com

Background and aims: Direct-acting antivirals (DAAs) revolutionized the treatment of chronic hepatitis C virus (HCV) infection. Viable hepatocellular carcinoma (HCC) has been identified as one of the few predictors of non-response to hepatitis C treatment with DAAs. However, it is still unclear why patients with HCC have a lower response to DAAs. Several hypotheses have been raised, including the possible role of HCC as a viral reservoir during antiviral treatment. We aim to assess if HCC acts as a viral reservoir for HCV during treatment of hepatitis C with DAAs.

Method: We characterized quantitatively the presence of HCV in liver explant tissue (obtained during transplant surgery) from a cirrhotic patient with viable HCC. The patient was chronically infected with HCV genotype 3 and at the time of surgery was completing his first month of treatment with sofosbuvir/daclatasvir. HCV quantification was performed with immunofluorescence targeting non-structural protein 3 (NS3). Tissue samples were evaluated through widefield microscopy with Zeiss (R) Observer. Intensity of fluorescence was quantified in Fiji (R) program and compared between HCC and non-tumoral liver tissue regions. Statistical analyses were performed using GraphPad (R), and One-way ANOVA between all groups was calculated. Differences were considered statistically significant when $p < 0.05$ (two-sided). This project is approved by the institutional Ethics Committee.

Results: In this patient undergoing treatment with sofosbuvir + daclatasvir for one month, we found significantly higher levels of immunofluorescence for HCV in the viable HCC tissue than in the non-tumoral liver cirrhosis tissue: fluorescence intensity/area was 55.8 ± 31.5 in tumoral tissue vs 0.6 ± 0.3 in non-tumoral tissue ($p < 0.05$)-representing higher density of HCV in HCC tissue than in the remainder cirrhosis non-tumoral tissue.

Conclusion: The present results suggest that HCV clearance is delayed in HCC tissue, compared to non-tumoral cirrhosis liver tissue. HCC may, then, act as viral reservoir for HCV during treatment with DAAs. Further studies are needed to confirm this hypothesis.

THU-371

Impact of a simplified diagnosis-monitoring strategy on Glecaprevir/Pibrentasvir (G/P) treatment initiation and response in patients with chronic hepatitis C virus (HCV) infection receiving opioid substitute therapy in Israel—a real world evidence

Eli Zuckerman¹, Orly Azulay². ¹Liver Unit, Carmel Medical Center, Technion Faculty of Medicine, Haifa; ²Liver Unit, Carmel Medical Center, Haifa, Israel
Email: elizuc56@gmail.com

Background and aims: Although HCV treatment for patients who using drugs (PWIDs) has shown good outcome and is recommended by international guidelines, treatment uptake has remained low. The primary objective was to assess the impact of active intervention model (“simplified”) versus conventional approach on treatment initiation and response in patients with chronic HCV infection receiving Opioid-Substitute Therapy (OST) in methadone Clinics in Israel.

Method: The data was collected from one Drug Maintenance Treatment Center (DMTC) in Haifa, containing 324 HCV-Ab-positive patients out of approximately 500 PWIDs treated with OST. Group A

(“simplified” approach) included 81 patients tested and prescribed with G/P at the DMTC during 2020–2023. The nurse reviewed the patients’ charts, withdrew blood sample included HCV RNA, blood count and chemistry and then performed fibroscan as needed while treatment (G/P) was prescribed by the hepatologist. Follow-up was performed by the Liver Unit staff. Group B- included 50 patients complete all required pre-treatment testing at the community clinics and were referred to the Liver Unit at Carmel Medical Center (up to December 31, 2019).

Results: Mean age was similar in both groups (49.2 and 50.8 years, respectively). Fibrosis assessment either by fibroscan or fib4 score was available in all patients from group A and in 32/50 in group B. The proportion of patients with advanced disease (F3–4) was significantly higher in group A (28% vs 15%, $p < 0.05$). The mean time elapsed from diagnosis of HCV infection to treatment initiation was significantly shorter in Group B (48 vs 126 months, respectively, $p < 0.0001$) and the same applies to the time from diagnosis to the first HCV PCR-negative test (94 vs 136 months, $p < 0.0001$). In Group A, the mean time elapsed from the time of intervention to treatment initiation was 9.25 months (range 0–33 months). In 74 of 81 of Group A (91%) and in 36 of 50 (72%) of group B, PCR results to determine SVR were available. SVR was achieved in 72 patients of group A (97%) and in 32 patients in group B (88%). Seven patients lost to follow-up in group A and fourteen in group B. In intention-to-treat analysis the SVR rate was significantly higher in group A ($p < 0.05$).

Conclusion: “Simplified” model applied in very difficult-to-treat OST patients is effective in reducing time of linkage-to-care and of treatment initiation and increasing the rate of SVR. However, even in this model in “real world” setting, we have faced barriers to better management of these patients.

THU-372-YI

Point of care hepatitis C screening and treatment among people who use drugs in new york city addiction centers: barriers and opportunities

Jessica Siguencia¹, Jhané Phanor¹, Anthony Choi¹, Robert S. Brown, Jr¹, Laura Maroldo².¹Weill Cornell Medicine, New York, United States; ²West Midtown Medical Group, New York, United States
Email: jms4007@med.cornell.edu

Background and aims: Among people who use drugs (PWUDs) in the US, Hepatitis C Virus (HCV) is prevalent in 70% and is often untreated due to limited access to testing and care. The addiction care setting provides a unique opportunity to bridge this accessibility gap by including point-of-care (POC) HCV testing among services used by PWUDs. The AbbVie B20 Study is a randomized study of test, educate, and treat in two drug addiction centers in New York City. Our preliminary results provide lessons on the significant challenges facing HCV screening and treatment in addiction centers.

Method: Patients in addiction care settings were recruited and screened for HCV infection, using HCV antibody with reflex RNA test, and a POC Cepheid HCV Viremia (RNA) test. The ongoing trial randomizes all eligible patients to a video-based patient education and treatment at the drug treatment program versus a standard of care (SOC) referral for Hospital clinic-based HCV therapy.

Results: Out of 12 addiction care locations in New York City contacted, only 2 locations participated, and 21 patients have been screened so far. At site 1, a residential drug and alcohol rehabilitation center, 9 of 148 residents consented. These 9 patients’ HCV results came back negative. The most common barriers to participation included unwillingness to interact with a medical team, aversion to undergo phlebotomy, prior negative HCV status, and competing priorities in the rehabilitation center. At site 2, a walk-in addiction treatment center, 11 of 15 patients were screened, seven participants were identified as HCV positive. Three of the seven were randomized to SOC and none came to our clinic. After missing SOC appointments, two of the three SOC patients began medication at the addiction center and have SVR pending. The last SOC patient never began

medication due to competing health priorities, which resulted in an emergency room admission. The remaining four participants were randomized to the test-and-treat arm and could start treatment at the site after completing video-based education. Two out of the four struggled with returning to the site for medication initiation and they have yet to reconnect with the facility. Out of the remaining two test-and-treat participants, one lost and stopped taking medication but returned 4 months later to restart medication. The last participant completed medication and had a confirmed sustained virologic response (SVR).

Conclusion: Substantial barriers exist at the individual patient level to HCV treatment, even when a medical provider provides POC testing and therapy. POC testing, ideally without phlebotomy, and treatment is essential for HCV eradication. Strategies to implement mental health services along with a test-and-treat strategy may allow us to overcome the identified barriers to initiating and completing HCV treatment in this vulnerable population.

Quality of etiotropic therapy efficacy of chronic hepatitis C patients in accordance of toll-like receptor 4 +3725G/C gene polymorphisms variety

Tetiana Bevz¹, Larysa Moroz¹, Kiarina Myroniuk-Konstantynovych¹, Iryna Bondaruk¹, Galyna Martyniuk², Yaroslav Demchyshyn¹.

¹National Pirogov Memorial Medical University, Vinnytsia, Ukraine;

²Central City Hospital, Rivne, Ukraine

Email: tasya241@gmail.com

Background and aims: Antiviral therapy is considered to be the only method that can stop the progression HCV infection, the development of hepatocellular carcinoma and death. The end point of antiviral therapy is the achievement of a sustained virologic response (SVR), which in 99% of cases is associated with the possibility of complete elimination of the virus. The aim of our study was to assess the dependence of the frequency of obtaining a SVR to antiviral therapy on the +3725G/C polymorphism of the toll-like receptor 4 (TLR4) gene.

Method: 111 chronic hepatitis C (1b genotype), patients (78 males, 33 females) were observed. All participants received antiviral treatment with Sofosbuvir/Ledipasvir. The duration of antiviral therapy was 12 weeks in patients without cirrhosis and 24 weeks in patients with liver cirrhosis.

Results: The vast majority of treated patients achieved a SVR (91.89%), the antiviral therapy was ineffective for 9 patients (8.11%). The number of non-RSVs was significantly ($p < 0.05$) higher among patients with the +3725C allele of the TLR4 gene (GC and CC genotypes)-77.8% of all those who did not respond to treatment were carriers of this allele. It was established that among patients with the GG genotype, only 2.41% of patients with chronic hepatitis C did not have a SVR. According to the results of the genotypes distribution comparison according to variants of the TLR4 gene +3725G/C allelic polymorphism by the exact two-tailed Fisher test among patients with chronic hepatitis C who had received antiviral therapy, the significantly higher frequency of carriers of the +3725G allele (genotypes GG and GC) was detected ($p < 0.001$) in the group of patients with RSV vs. the group of patients who did not receive a SVR. According to the odds ratio calculations, it was established that individuals carrying the +3725G allele of the TLR4 gene have a 13 fold higher chance of obtaining a SVR during antiviral therapy use (OR = 13.5; CI 2.61, 69.81). It was established that in the vast majority of patients (68.63% [n = 70]) with chronic hepatitis C, whom a SVR was obtained in, absent liver fibrotic changes (F0) or initial stages of liver fibrosis were observed in 2.26 fold higher number of patients vs. ones with liver fibrosis/cirrhosis (F3-F4). Among non-RSV patients, the degree of liver fibrosis F0-F2 were not detected.

Conclusion: Among patients with chronic hepatitis C who did not have a SVR to administered antiviral therapy, there were 3.2 fold higher number of patients with severe liver fibrosis/cirrhosis (F3-F4).

POSTER PRESENTATIONS

Most of the patients (77.8%) who did not achieve a SVR were carriers of the +3725C allele of the TLR4 gene ($p < 0.05$). The odds ratios of achieving a SVR in patients with chronic hepatitis C with the 1b genotype were 13 fold higher among carriers of the +3725G allele of the TLR4 gene than among carriers of the +3725C allele.

Email: soo.aleman@regionstockholm.se

Background and aims: A previously published real-world data analysis demonstrated high effectiveness of sofosbuvir/velpatasvir (SOF/VEL) in >6, 000 HCV patients from 12 clinical cohorts across Australia, Canada, Europe and USA. Irrespective of age, male patients were more likely to have advanced fibrosis and infection with HCV GT 3, and median time to treatment initiation was numerically shorter in male patients across the age spectrum. The aim of this large real-world analysis was to evaluate characteristics of an expanded pool of HCV patients treated with SOF/VEL across regions globally.

Method: This analysis included patients ≥ 18 years treated with SOF/VEL without ribavirin (RBV) for 12 weeks from 7 sites across Hong Kong, Mexico, Sweden, Spain, Taiwan, and the United Arab Emirates. Baseline characteristics, such as age (in categories $< / \geq 50$ yo), sex, being treatment experienced (TE), cirrhosis presence (F4, no decompensated), genotype, coinfections (HBV, HDV, HIV), time to treatment initiation (TTI) from HCV diagnosis were described, along with sustained virology response rates (SVR) (4/12/24).

Results: Among 4, 679 patients, 59% (2, 760) were males and 41% (1, 919) were females, with 73% females vs 64% males being ≥ 50 yo ($p < 0.001$). Coinfections were more prevalent in males (HIV 6.9% vs 1.6% $p < 0.001$; HBV 4.9% vs 3.4%, $p = 0.005$; HDV 0.2% vs 0.1%, $p < 0.001$), they were more often TE (5.9% vs 3.9%, $p = 0.001$) and more often had GT3 (24.2% vs 17.6%, $p < 0.001$); these differences were seen mostly in males ≥ 50 yo. No differences by sex was observed for patients with compensated cirrhosis (19.9% male vs 21.7% female, $p = 0.34$). Time to treatment initiation with the HCV therapy was shorter in females aged ≥ 50 yo, with 23% treated in the first month, as compared to 16% of males above 50 yo ($p < 0.001$). In 4, 195 patients with SVR

outcomes (effectiveness population), both sex and age groups had SVR greater than 97%, showing a statistically significant difference between female and male patients aged ≥ 50 yo (99.4% vs 98.5%; $p = 0.0266$).

Conclusion: This new analysis confirms the high effectiveness of using SOF/VEL in diverse populations globally, with real-world SVR higher than 97% across diverse age, sex and geographic groups.

THU-375

When glecaprevir/pibrentasvir ultra-short therapy is enough to eradicate HCV infection

Alberto Grassi¹, Natascia Celli², Silvana Maccariello², Gabriele Donati³, Angela Fabbri², Giorgio Ballardini². ¹Ospedale Cervesi, Cattolica (RN), AUSL della Romagna, Cattolica (RN), Italy; ²Internal Medicine Unit, Infermi Hospital, Rimini, Italy; ³Internal Medicine Unit, State Hospital of San Marino, Borgo Maggiore, San Marino
Email: albgrassi@yahoo.com

Background and aims: There is general agreement about the fact that at least 8 weeks of therapy with direct antiviral agents (DAAs) are necessary to achieve definitive hepatitis C virus (HCV) eradication but, probably, the real impact of DAAs in HCV replication is not yet completely known.

Method: From 2018 to 2023, 302 HCV-RNA+ patients received antiviral treatment with glecaprevir/pibrentasvir (G/P) and completed 12 weeks post-treatment follow-up.

Results: Sustained virological response (SVR) was globally obtained in 297 patients (98.3%). Ten patients prematurely suspended treatment, mainly for light side effects (itching, headache weakness). The main characteristics of patients are the following: median age (years): 63 (40–83); male/female: 7/3; liver fibrosis score (metavir): 3 F 1, 3 F 2, 2 F 3, 2 F 4; genotype (G): 3 G 1, 3 G 2, 3 G 3, 1 G 4; median pre-treatment HCV RNA (log IU): 5 (4–7); median pre-treatment alanine transaminase (ALT) (IU): 54 (6–248); median duration of treatment (days): 7 (4–28). Nine of them (90%) were HCV RNA negative at the end of treatment and six of them (60%) resulted SVR; three (30%) relapsed 12 weeks post the end of treatment and only one (10%) resulted non-responder. SVR patients showed pre-treatment ALT level lower than non SVR patients (IU median values: 39 vs 131, $p = 0.017$). Age, gender, liver fibrosis score, genotype, pre-treatment HCV RNA and duration of therapy were not significantly different in the two groups.

Conclusion: In this tiny series of patients, HCV eradication was obtained in 60% of cases with (even extremely) reduced duration of treatment with G/P. Apparently SVR resulted more probable when pre-treatment degree of HCV related hepatic cytonecrosis was low. More studies about this topic would be important to eventually permit ultra-short scheduled of treatment to eradicate HCV infection. This should strengthen the case for offering treatment with DAAs to all HCV+ people, even to subjects with presumed reduced compliance with therapy (prisoners, drug addicts, etc) in accordance with the World Health Organisation (WHO) program to eliminate HCV infection within 2030.
